
The Evans Hydraulic Elevator,

— MANUFACTURED BY —

RISDON IRON WORKS, San Francisco.

Used in Unwatering the Comstock Lode.

Send for Catalogue No. 5.

The cheapest and most efficient Water Elevator made.

It will do more and better work than any other Gravel Elevator.

It is fully protected by United States and Canadian letters patent.

See those wires -- how they interlock? Note the smooth surface also.
No displacement of wires in any event. Gives three times the service of other cables, and adds correspondingly to the life of the rolling stock.

—THE PATENT—

Locked-Coil  Track Cable

Is Used only on the Patent

BLEICHERT WIRE ROPE TRAMWAY,

and Others Manufactured by

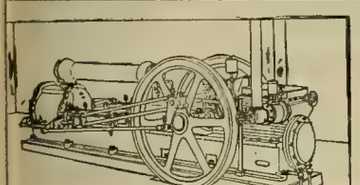
THE TRENTON IRON COMPANY, Trenton, N. J.

ENGINEERS AND CONTRACTORS,

and Sole Licensees in North America for the Bleichert System. Also, Wire Rope Equipments for Surface and Underground Haulage, Transmission of Power, Etc. Illustrated Book Upon Application.

For Particulars, Address, **NEWTON M. BELL, Agent, 109 California St., San Francisco.**

☞A full stock of the Trenton Iron Co.'s Wire Ropes, made from "SPECIAL" Crucible and Plough Steel, carried in San Francisco.



THE NORWALK Air and Gas Compressor.

In use in every State in the Union, Central and South America, Great Britain, etc. Also by the U. S. Army and Navy.

ESPECIALLY DESIGNED FOR DRIVING

Rock Drills, Pneumatic Locomotives, Engines, Pumps, Coal Cutters,

and Other Mining Machinery. The Best Machine for Compressing Air for All Dynamic Purposes. Send for Illustrated Descriptive Catalogue.

Mining and Metallurgy.

The latest and best books can be had from the book Department of the MINING AND SCIENTIFIC PRESS at best prices. ALL BOOKS SENT POSTPAID. Following is a partial list:

ASSAYING:—PART I—GOLD AND SILVER ORES.
Third edition; Rewritten and Improved by the Author, C. H. Aaron; 130 pages, illustrated....$1

ASSAYING:—PARTS II & III—GOLD AND SILVER BULLION, LEAD, COPPER, TIN, ETC.
Latest edition; 161 pages, illustrated, cloth. Much of the original text replaced by new matter....$1 75

PROSPECTOR'S FIELD BOOK AND GUIDE:
By H. S. Osborn....$1 50

ROASTING OF GOLD AND SILVER ORES AND THE EXTRACTION OF THEIR RESPECTIVE METALS WITHOUT QUICKSILVER:
Second edition; Guido Kustel, M. E.; 156 pages, with illustrations of furnaces, supplements and working apparatus....$3

PRACTICAL TREATISE ON HYDRAULIC MINING:
By Aug. J. Bowie, Jr. On the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on heavy grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc....$5

PRACTICAL HYDRAULICS:
A book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers and Irrigators. By P. M. Randall. Contains useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulæ, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules and tables are prepared. Is specially applicable to the Pacific Coast....$2

MODERN COPPER SMELTING:
E. Dyer Peters, Jr. Eighth edition. Rewritten and enlarged. Profusely illustrated....$5

STAMP MILLING OF GOLD ORES:
By T. A. Rickard, M. E. An actual record of milling practice in this and other countries. Deals with the erection and management of mills, and contains many helpful suggestions. Well illustrated. Cloth....$2 50

MINERS' POCKETBOOK:
A reference book for miners, mine surveyors, geologists, mineralogists, millmen, assayers and metallurgists. By C. G. W. Lock. 472 pages, illustrated, flexible leather....$5

MANUAL OF MINING:
For the use of Mining Engineers and Technical Schools. Treating of Preparatory and Exploratory Work, Methods of Mining, Hoisting Machinery, Pumping, Ventilation Shafts, Tunnels, Blasting, Timbering, etc., etc. By Prof. Magnus C. Ihlseng, E. M., Ph. D. Third, revised and enlarged, edition. 548 pages, 8vo., cloth....$4

QUARTZ OPERATOR'S HANDBOOK:
By P. M. Randall....$2

ALLOYS:
Thurston, 2nd edition....$2 50

ASSAYING:
Furman, 4th edition....$3

HIGH EXPLOSIVES:
Eissler....$4

GOLD ORES:
Treatment of; O'Driscoll....$2

GEOLOGY:
Emmons, $1 50; Scott, $1 90; Le Conte, revised edition, $4; Dana, 4th edition....$5

IRON AND STEEL:
Thurston, 6th edition....$3 50

LITHOLOGY:
Williams, 2nd edition....$3

LIEBER'S CODE:
Bound in leather....$3

PATENTS

DEWEY, STRONG & CO'S PATENT AGENCY.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American reports, with full copies of U. S. Patents since 1872. All worthy inventions patented through DEWEY, STRONG & CO.'s Patent Agency will have the benefit of a description in the *Mining and Scientific Press*. We transact every branch of patent business, and obtain patents in all countries which grant protection to inventors. The large majority of U. S. and foreign patents issued to inventors on the Pacific Coast have been obtained through our agency. We can give the best and *most reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and circulars free.

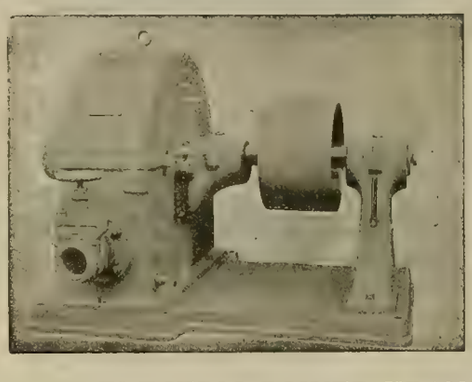
The Pelton Water Wheel Company



Gives exclusive attention to the development and utilization of water powers by the most modern, economic and improved methods.

An experience of more than fifteen years, involving both the theory and practice of hydraulic engineering as relates to power development in its widest range of application, is at the service of its customers.

Nine Thousand Wheels Now Running,

Aggregating some 700,000 H. P.

ELECTRIC POWER TRANSMISSION.

Pelton wheels afford the most reliable and efficient power for such service and are running the majority of stations of this character in the United States, as well as most foreign countries.

Highest efficiency and absolute regulation guaranteed under the most extreme variations of load.

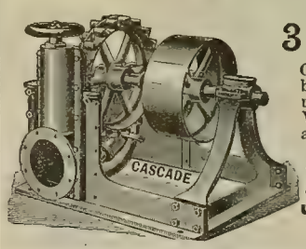
The Pelton Water Wheel Company,

121 AND 123 MAIN STREET, SAN FRANCISCO, CAL.

TURBINE AND CASCADE WATER WHEEL

Adapted to all Heads from

3 Feet to 2000 Feet.



Our experience of 33 YEARS building Water Wheels enables us to suit every requirement of Water Power Plants. We guarantee satisfaction.

Send for a Pamphlet of either Wheel and write full particulars.

JAMES LEFFEL & CO.
SPRINGFIELD, OHIO, U. S. A.

C. H. EVANS & CO.

HAVE REMOVED THEIR

Machine Works

TO 183-185-187 FREMONT STREET,

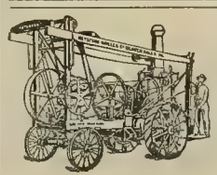
Where, with Enlarged and Increased Facilities, they are better than ever prepared to do

First-Class Machine Work

Promptly, and at Reasonable Prices, and will continue the manufacture of

Thomson & Evans Steam Pumps,

Deep Well Pumps, Power Pumps, Etc.,
Also Marine Engines, Ship and Steamboat Work, Pipe Cutting, General Jobbing and Repairing.



For Testing Placer Ground.

Sinks and drives 6, 8 or 10-inch pipe through boulders; takes all the loose material out, including gold, as the hole is sunk. Does the work at a very small cost. Drills water and oil wells and mineral test wells through any kind of rock to 1500 feet. Several sizes.

Write for Catalogue and full information.

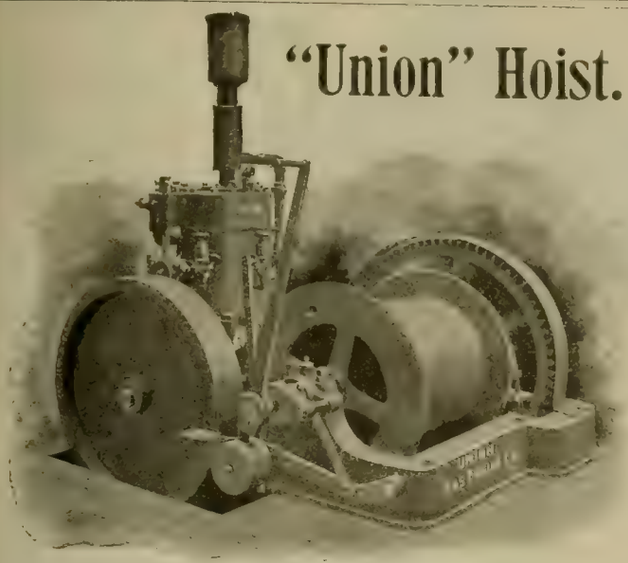
KEYSTONE DRILLER CO., Beaver Falls, Pa.

THE RISDON HAMMERED SHOES AND DIES

Manufactured from the best quality of projectile steel—which is stronger and tougher than any heretofore used—the best shoe and die ever made. Will crush more ore per pound of steel than any other. Will not chip or cup and will outcrush any other made. Wear smooth and true with hardly any perceptible decrease in their size, and those who use them say, "We never had shoes and dies wear so long." Send for circulars and dimension blanks to

THE RISDON IRON WORKS, SAN FRANCISCO.

"Union" Hoist.



The above cut represents our 10 h. p. Double Cylinder Engine of latest type, and Hoist combined on strong iron base. This hoist is designed to raise one ton125 feet per minute from an inclined shaft, or 1500 pounds at the same speed vertical lift. The drum will hold over600 feet of ⅝-inch cable. The outfit weighs 3500 pounds.

THE UNION GAS ENGINE CO.

—BUILD THE—

"Union" Gas Engines,

Which use either Manufactured or Natural Gas, Ordinary Stove Gasoline (Naphtha or Benzine), Distillate or Kerosene.

STATIONARY ENGINES for All Kinds of Work, Built in Sizes from 3 to 200 h. p.
"UNION" COMBINED HOISTS in Sizes from 2 to 40 h. p.
"UNION" COMBINED COMPRESSORS—20, 30, 40 h. p.
HOISTS and COMPRESSORS Can Be Built in Larger Sizes to Order.
"UNION" MARINE ENGINES, 4 to 200 h. p., of Single, Double and Four-Cylinder Types.
TEN YEARS' EXPERIENCE Building Gas and Oil Engines.
"UNION" ENGINES Are In Use All Over the United States.
"UNION" ENGINES Are Simple, Durable and Economical.

FRESNO, June 25, 1898

Hercules Gas Engine Works, San Francisco, Cal.

DEAR SIRS:—

The fifteen-horse power gasoline engine and hoist purchased from you is doing fine work and is perfectly satisfactory in every respect.

Yours truly,

TUOLUMNE MOTHER LODE M. & D. CO.,

Per N. W. Moodey, Pres.

We have two large books full of testimonials; they speak better for the HERCULES than we can. Our works are the largest in the country. We have built and sold over 3500 engines; they are the standard everywhere. Any size up to 200 H. P. Stationary, Hoisting and Marine.

Assessment Notices.

MARINA MARSICANO GOLD MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Sunny Hill, Shasta County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 7th day of January, 1899, an assessment (No. 17) of 4 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, 217 Sacramento street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 21st day of February, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 13th day of March, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CHARLES BOVONE, Secretary.

Office—217 Sacramento street, San Francisco, California.

SIERRA NEVADA SILVER MINING COMPANY. Location of principal place of business, San Francisco, California; location of works, Virginia Mining District, Storey County, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 18th day of January, 1899, an assessment (No. 15) of Twenty cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, Room 14 Nevada Block, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on TUESDAY, the 21st day of February, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 13th day of March, 1899, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

E. L. PARKER, Secretary.

Office—Room 14 Nevada Block, No. 309 Montgomery street, San Francisco, California.

EUREKA CONSOLIDATED DRIFT MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Forest Hill.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 26th day of January, 1899, an assessment (No. 16) of one-half cent per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 1209 Claus Spreckels building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 24th day of February, 1899, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on SATURDAY, the 11th day of March, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

J. J. CRAWFORD, Secretary.

Office—1209 Claus Spreckels building, San Francisco, California.

JUNCTION MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Tuolumne County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 4th day of February, 1899, an assessment (No. 23) of three (3) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, 106 Leidesdorff street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 13th day of March, 1899, will be delinquent and advertised for sale at public auction, and, unless payment is made before, will be sold on MONDAY, the 3rd day of April, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CALVERT MEADE, Secretary.

Office—106 Leidesdorff street, San Francisco, California.

ORLEANS MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Grass Valley, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 8th day of February, 1899, an assessment (No. 8, new series) of seven (7) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 324 Pine St., San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 14th day of March, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 5th day of April, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

MINING AND SCIENTIFIC PRESS.

AND PACIFIC ELECTRICAL REVIEW.

No. 2016.— VOLUME LXXVIII. Number 8. SAN FRANCISCO, SATURDAY, FEBRUARY 25, 1899. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

An Idaho Hydraulic Mining Enterprise.

As in all forms of gold securing, hydraulic mining is a progressive science. Based on what was invented nearly fifty years ago in California, and accompanied by California additions and improvements in after years, there is no part of any surface gold-producing region of the earth in which the scientific evolution of the California hydraulic methods is not in operation. The skill of the engineer, with the sums at the disposal of modern mining corporations, successfully solve problems that once seemed insuperable, it often appearing that the greater the obstacles the greater the incentive to overcome them.

Recently appeared in these columns a technical, illustrated account of the great hydraulic enterprise which a French company had successfully completed in Trinity Co., Cal. A similar work, just completed in Idaho, appears to deserve as wide publicity. In the Boise basin, Idaho, the Twin Springs Placer Co. has expended several hundred thousand dollars in preparatory work of unusual magnitude, interesting in its construction to mining engineers. Among other problems presented was the task of successfully carrying a necessarily large volume of water through an unusually large pipe over a depression of 350 feet. Thirty years ago Jos. McGillivray brought a 15-inch pipe over a depression of 240 feet and across the Trinity river, Trinity Co., Cal.; twenty-eight years ago the Spring Valley Mining Co. put in a similar

INVERTED SIPHON OVER BOISE RIVER, TWIN SPRINGS PLACER COMPANY, BOISE, IDAHO.

VIEW OF FLUME AND HYDRAULIC WORK, TWIN SPRINGS PLACER COMPANY, BOISE RIVER, IDAHO.

contrivance at Cherokee, Butte Co., Cal.—a wrought iron, riveted, 30 inch pipe, 14,000 feet long, across a depression of about 950 feet. To this latter enterprise was first applied the term "inverted siphon." Such aqueducts do not work on the principle of the siphon, and are thus far misnamed. They utilize the pressure of the water at the inlet to maintain a regular, steady flow, forcing the water of the outlet branch or arm of a V-shaped pipe line out at a point slightly below the level of the inlet. In this way water is carried at great head and tremendous pressure, in considerable volume, in large pipes across rivers, up and down the sloping sides of canyons, to where its use is desired.

Herewith are two engravings from photographs taken especially for this article, the first graphically portraying the transit of the water of Sheep creek in the big pipe, down to and across the Boise river, and up the precipitous slopes, on, over the crest of the ridge, and down to where the extensive gravel deposits of the company are to be worked. That portion of the pipe constituting the "inverted siphon" is 1700 feet in length and 48 inches in diameter. This pipe is made with an expansion joint, one of these joints being placed between each two elbows. It is calculated that the pressure per square inch in the lower portion is 167 pounds. The pipe was laid and the work finished last August. Since its completion, hydraulicking showed the profitable character of the ground, which is locally reported to average about 40 cents per cubic yard, the duty there of 1 miner's inch of water being 2.3 cubic yards per twenty-four hours. The company has eight placer mines in the Boise basin, and from Aug. 16th to Nov. 16th, '98, cleaned up an average of nearly $1000 per day therefrom.

The Reardon Patent Air Hose Coupling.

The accompanying illustration shows the Reardon patent hose coupling, especially designed for coupling air drill hose to rock drills, made in either straight or bent form. The bent form does away with the breakage of the hose close to the coupling, caused by the weight of the hose when attached to the drill by the old style straight coupling; it is easily connected, cast with a round thread on one end, which screws into the hose. A special band is bolted around the hose above the threaded part of the coupling and securely clamps it, preventing the couplings working loose. When the hose is disconnected, the face or joint of the coupling is protected from damage by a heavy coupling collar. The straight form is made for use at the other end of the hose, where it is connected to the main air pipe. It is made by the Compressed Air Machinery Co., 11-13 First street, San Francisco, Cal., and is a ready seller.

Patents for Pacific Coast Inventors; Notices of Recent Patents, 214.

TRADE follows the flag—sometimes; but it always follows the price list.

THE California effort to create the office of mine inspector has failed. Several of the mining States have such officers, and the appointment would have been in line with needed progress.

IN connection with electrical requirements it is probable that one of the first results in a further advance in the price of copper would be an effort at reduction of cost of producing aluminum, that metal having been proved by recent experiments particularly adapted to the economical transmission of electrical power.

THE statement that no paying mines exist in Colorado below 7500 feet altitude is noticeable. High altitudes prevail throughout all Colorado, and the paying mines are located above the altitude indicated, this condition being in contrast to other mining regions. Only a few of California's large mines are found above 2500 feet altitude, and most of them are but 1000 to 2000 feet above the sea at the surface, their lower workings extending in many cases several hundred feet below the level of the sea.

THE Colorado decision noted at length last week has resulted at Leadville in claim jumping on a large scale. According to reports, stakes were being driven in 5 feet of snow and nearly 100 acres of valuable mining territory in the heart of Leadville has been staked out by representatives of one mining company. These locations in the snow are made because of the Mt. Rosa decision, in which it was held that a lode location on a placer claim could be only 50 feet wide instead of 300 feet wide. Mining men there are greatly disturbed over the decision and considerable resultant litigation is expected.

THE Circuit Court of Appeals this week decided the suit between the Boston & Montana and Montana Ore Purchasing Companies, reversing the decision of the lower court which had granted the injunction prayed for and ordering the suit dismissed. The B. & M., plaintiffs, claimed that defendants, M. O. P. Co., were extracting ore from their claim, and asked for $500,000 damages. In March, '97, the Montana court granted the injunction asked for by plaintiffs. In April, '98, the Circuit Court of Appeals at San Francisco, Cal., set that injunction aside, alleging no jurisdiction on the part of the lower court. Plaintiff amended complaint, the Montana court again granted the injunction, and again the Appellate Court sets it aside, this time ordering the case dismissed on the ground that no federal question is involved.

Lead Miners and Smelters' Rates.

Several letters are received this month, inquiring as to phases of the lead market, and the considerable figure the smelters cut therein, and a few general statements on that whole subject are deemed advisable.

The Canadian Commission has been unsuccessful in an effort to get lead on the free list: on all lead in ore, or lead ore imported into the U. S., there is a duty of 1½ cents per pound. There are several large concerns engaged in the business of smelting lead ores, not exclusively, but in connection with the smelting of other metals. The largest on the Pacific coast is the Selby Smelting & Lead Works of San Francisco. Among the largest smelters operated in Colorado is one by the Kansas City Consolidated Smelting & Refining Co. at Leadville.

Whether the lead ore be shipped from Mexico or Canada, or be of domestic production, its two principal domestic markets are St. Louis and New York City. The Colorado and coast smelters buy on the New York quotations, current; that is, whatever smelter quotations of lead—"brokers' prices"—are in New York the day returns are made from the smelter, govern the price paid. The returns are a very variable quantity, being determined by the ore itself, and the ruling market rate. Usually Colorado smelters produce pig lead on a basis of so much per unit on a $4 price per 100 pounds, the difference between that and the current quotation governing the per unit price. The "unit" means one per cent. If a smelter pays so much per unit, it is a trade way of saying so much for every one per cent in the lead ore. Suppose it is an 18% ore: then, if the smelter pays 25 cents per unit, that would be $4.50 per ton for the lead in the ore; "25% ore" means that in a ton of that ore there would be 500 pounds metallic lead; in the case mentioned that would mean $4.50÷500—.9 cents per pound.

All this is a sort of kindergarten proposition to smelter men and sellers of ore, but there are others to whom a few figures are interesting. Among the letters referred to is one from two Colorado men saying that in their experience with smelters they got "very little credit for the lead" in their ore, and implying that the smelter people are in some way getting the best of them. This is unlikely, but, if so, the Colorado shippers have the remedy in their own hands. There is as much competition and close figuring in the smelter business as in any other line, and the shipper will naturally go where he can get the best returns. New York quotations govern the price; ofttimes the freight and treatment charges eat up considerable of the margin of possible profit to the producer, though in most smelting establishments treatment charges are largely determined by the amount of lead in the ore, and it is not infrequent that because of this the shipper gets more for his ore than would appear, the treatment charges being modified by the amount of lead in the ore, thus constituting an indirect payment therefor.

Taking up the Colorado method as between the miner and smelter, the former can easily find out what the latter will pay. His ore may go 15, 25 or 40 units; the smelter replies to his inquiry with a schedule, saying, virtually:

We will pay for lead ores as follows, $4 basis New York quotation day of settlement, ore containing lead from 10% to 15%, inclusive, 20c per unit; 15% to 20%, inclusive, 25c per unit; 20% to 30%, inclusive, 35c per unit; 30% to 45%, inclusive, 45c per unit; 40% to 50%, inclusive, 55c per unit.

Of course, as hitherto noted, the higher the percentage the less the proportional cost; there are certain fixed charges that must be met, whatever may or may not be in the ore, but it being usually a self-fluxing proposition the treatment charges are less, proportionately, as between dry and wet ore.

Assuming for illustration that the Colorado shipper has made up his mind where he wants to send his ore with best possible returns to himself, taking into consideration freights, etc., and that he has sent lead ore that contains 40%, he will get thereon 45 cents per unit on a $4 basis. The New York quotation on the day of settlement is another factor in the result; assuming that it was $3.85, the difference would be 15 cents, one-fifth for treatment is 3 cents, which, taken away from 45, leaves 42 cents, the net price. This, multiplied by 40, gives $16.80 per ton for the lead in the ore; the 5 used for dividing the 15 is represented by the fact that the smelter's quotation to the miner is on the unit or 20 lbs., while the New York quotation is five times that, or 100 lbs. All this on a $3.85 basis. Lead has advanced—quoted to-day at $4 20, or 35 cents more. Now, if at $3.85 the net unit price on a 40% ore would be 42 cents, at $4.20 it would be 49 cents, the last number being found by adding to the 42 one-fifth the advance in the price.

There is nothing new or original herein; it is merely a compilation of statements from several sources, being an effort to state plainly the facts.

Temperature of Battery Water.

"The temperature of battery water" is receiving the attention of many mill men, and from the variety of opinions published herein, based on personal experiment, it would appear that other conditions than the temperature of the water are important factors in amalgamation of gold ores in batteries and on plates. At the Homestake mills, Lead City, S. D., the superintendent after a series of careful experiments lasting a considerable period determined to his own satisfaction that the best results were accomplished at a temperature of 52°. The temperature is obtained during winter by heating the water and in summer by pumping it to a tank located in a tower from which it was allowed to fall through screens, and exposed to the draft of revolving fans which reduced the temperature to the desired point. It may be that although 52° is the proper temperature at the Homestake mine, that this temperature would not be found to give the best results in Arizona or in California or Colorado.

That the character of the ore is an important factor there is little doubt, and there is reason to believe that the size of the gold particles may also have an important influence on the behavior of the quicksilver. In some ores the gold is in an extremely fine state of division; in others it is comparatively coarse and it is not to be expected that two such widely different ores would act similarly even were the temperature of battery water the same in each case. Many mill foremen take careful note of the result of the operations in their mills under varying conditions; some are satisfied to let well enough alone and often claim they are accomplishing the best possible results, when they really do not know such to be the case.

THE location of numerous claims by single individuals in any one district is a subject for legislation. In a single district in San Diego county, California, one man had located 160 claims. These required by law the performance of $16,000 in labor or other improvements annually, but the claim holder did not spend $160 on the entire lot, still he could and did keep other men who were willing to work from locating any of his claims. This wholesale location of mineral ground should not be permitted. Of course the new ninety-day law is calculated to make this impossible, but most men prefer not to undertake the location of a piece of ground in the face of an adverse claim and possibly expensive litigation, which is almost certain to result should he find a valuable ore body.

FROM nearly every elevated part of this west half of America come reports of unprecedented snowfall; in some parts of Colorado and Utah there was so much as to occasion serious financial loss and, in two or three instances, loss of life. The great snowfall insures a prosperous mining season everywhere that it made its temporarily unwelcome presence felt. In California considerable snow has fallen in the high Sierras, and should rain to any extent fall in the next ninety days in the foothill region, that comonwealth will share in the mining prosperity of its sister States during the remainder of '99.

THE Franklin Institute, Philadelphia, is preparing its 30th exhibition. It deserves respectful recognition for its great work through the century in fostering and chronicling the industrial and scientific achievements that have placed this country in the van. Every advance in knowledge made by man since 1826 is recorded in the archives of the Franklin Institute.

Concentrates.

SPOKANE, WASH., is about to organize an open mining stock exchange.

THE Red River, N. M., *News* says "every idle man in the camp is at work!"

A MINER'S inch of water is usually required for each battery of five stamps.

QUARTZ ROCK in place in the vein measures about 13 cubic feet to the ton—when broken 20 cubic feet to the ton.

A RECENT advance of 15% in the price of antimony leads to renewed interest in the Nevada and California deposits of that metal.

THE third session of the Mining Congress is to be at Milwaukee, Wis., next August. The first was in Denver, Colorado, July, '97; the second, Salt Lake City, Utah, July, '98.

THE mine tax proposition in Arizona now assumes the phase of a bill to tax mines in that Territory having a product of $50,000 or over per annum, a sort of income tax that would not abide.

WASHINGTON State papers justly argue that the levy of a mine assessment should be made a matter of sufficient publicity to insure knowledge of the fact on the part of the stockholders.

SINCE the stimulus of sulphur prices by the late Spanish war the U. S. sulphur output has been increased in a manner that appears to warrant permanency, being profitable even at peace prices.

THE new Washington State county of Republic, carved from Stevens Co., has a population of 2000, with Republic the county seat. It is claimed that there are 500 patented mining claims therein.

IN the mines of Cedros island, off the coast of Lower California native sulphur is found containing gold to the amount of $100 per ton. This sulphur has without doubt been derived from auriferous pyrite.

SINCE '93 little has been done in silver production in California; the largest silver-producing mines are in Inyo, Kern and San Bernardino counties; except as a "by-product," nothing is being done therein at present.

A MINING ENGINEER of Johannesburg, S. A. R., was recently sent to examine some mining properties near Gwelo, in the interior. He reports being unable to find the property at all. Similar occurrences have been heard of in America.

OF the $275,000,000 output of gold of the world during '98, A. Sauerbeck estimates that the United States has between $180,000,000 and $200,000,000. The large banks of England, Germany and France hold something less than $50,000,000 as compared with their holdings at the close of '96.

A BILL introduced in the California Legislature by Assemblyman Blood makes it a felony to make false oath setting forth the performance of $100 worth of labor on an unpatented mining claim. The punishment for such false swearing is fixed at one year's imprisonment in the county jail, $100 fine, or both.

SEVERAL of the largest smelters throughout the country are reported about to consolidate with a $50,000,000 capitalization. It is understood that as between the combine and the smelting establishments not included therein, existing arrangements regarding interchange of business, etc., will not be disturbed. Among those specified as being about to enter the combination none west of Utah are so far mentioned.

THE recent increased demand at the San Francisco and Philadelphia mints for $20 gold pieces is ascribed to a change of custom in Europe. Formerly gold bars were asked for by those who had shipments of large amounts to make to Europe, as the gold coin sent there was melted and recoined. Now the double eagles are kept. Russia alone has twenty million dollars in $20 gold pieces in her treasury and the Bank of England has a large amount.

SUCCESSFUL mining is neither the result of practical nor theoretical considerations separately and distinctly, but of both combined; for the theoretical man without practical knowledge is in the same position as the practical man without theoretical knowledge—both would be better with the combination. Practical men usually make the best theorists, for they know when a theory is required and the purpose it is intended to accomplish.

THE minimum diameters of sheaves over which steel wire ropes can be safely bent should be equal in inches to the diameter of the rope in inches multiplied by 50, and for pulleys for hoisting the minimum size should be equal to the diameter of the rope in inches, multiplied by 100. When the diameters of the sheaves are too small, the rope is injured and the lifetime of its use greatly shortened. When a hoisting rope is too heavy, it increases the difference of balance, and is subject to a wave movement caused by the load not keeping it taut, the result being that the cage jerks and jumps, the frame vibrating.

A CONTRIBUTOR furnishes the following decision of the State Supreme Court, omitting, however, to specify date and particular suit: "An appropriation of water by means of a ditch is not measured by the capacity of the ditch, but is limited to such quantity, not exceeding its capacity, as the appropriator may put to a useful purpose; and no matter how great in extent the original quantity appropriated may have been, any amount less than the whole amount appropriated, which has not been devoted to a beneficial use at some time within five years, is lost and forfeited as against a subsequent appropriator thereof."

TWO DISTINCT TYPES of distribution are used for incandescent lighting in this country, the single-phase alternating current and the direct current three-wire system. The former does not usually permit the supplying of power. As alternating distribution is at high potential, it does not permit the location of the station where the conditions of maximum economy can be fulfilled. The three-wire incandescent system, using low voltages, may be used for supplying motors, but the amount of copper necessitated by the low pressure has caused such stations to be located near the center of distribution, irrespective of the best conditions for the economical operation of the plant.

WOLFRAMITE is a native tungstate of iron and manganese, is generally a brownish or grayish black and has a reddish brown streak. The specific gravity, 7.2 to 7.5, is nearly equal to that of metallic iron. It occurs crystallized, also massive with lamellar structure. It is the ore from which the metal tungsten is usually obtained, and is often associated with tinstone. The metal tungsten is used to improve the quality of steel by being added in very small quantities. It is chemically related to molybdenum and uranium. The consumption of wolframite in the United States during '98 was about eighty tons. The ore has a market value of $17.60 per kilogram for lump and $42.84 for powdered ore—nearly $1.50 an ounce.

CAST IRON may be silvered without the intervention of copper or other primary coating by proceeding as follows: Dissolve thirty parts of crystallized silver nitrate in 150 parts of distilled water. Dissolve sixty parts of potassium cyanide (commercial 75%) in 100 parts of water and mix the solutions. Dissolve fifty parts of sodium chloride in 750 parts of distilled water, and to the solution add that of the silver cyanide, in a thin stream with constant agitation. Plunge the iron to be silvered in nitric acid of 1.20 s. g., and let remain for four or five minutes, and remove directly from the bath, after letting drain to get rid of surplus acid, into the silvering solution. Silvering is instantaneous, but the metal may be kept in the fluid for a few minutes. Remove, rinse, and with a burnisher rub down the surface.

FROM Jas. Arthur, Cornucopia, Or., is received an excellent sample of mica, of unusual size—5x6 inches. Mica is valued largely as to the size of the sheets procurable. Sheets 3x3 inches are worth $1 per pound; sheets 6x6, $10 per pound. The following in New York City deal in mica of marketable quality: J. D. Hague, E. V. Munsell, A. O. Shoonmaker, the Palermo Mica Co. Mr. Arthur says one sheet taken out is 22x26 inches. If so and the mica is of good commercial quality the depsit is a valuable one. He says the sample mailed is from one of seven claims in Idaho, seventeen miles from N. P. R. R. The mine has been developed by 2000 feet of tunnel on various claims and "1000 feet of shafting." An extended illustrated article on the mining and marketing of mica appeared in the issue of Nov. 26th, '98.

THE rich telluride ores of the Terry Peak region in the Black Hills of South Dakota occur in the Cambreo-Silurian (Potsdam) formation at several horizons and usually in the quarzite. These ore deposits almost invariably have a direct association with intrusive dykes of trachite, phonolite and other eruptives of somewhat similar type, and are frequently overlain or underlain by sheetlike masses of trachite or rhyolite, evidently forming a part of the great masses which have been erupted about Terry Peak. These ores are highly silicious, and usually of fine granular texture, no free gold can be obtained as a rule, though perhaps, exceptions occur. One of the most interesting occurrences of gold in that region was found in '81 in cherty masses (flint) in the limestone of the Pocahontas mine at Squaw creek.

TO ETCH an autograph on a silver plate, cover the plate with wax, etcher, varnish, or paraffin, making a thin and even coating of the protecting agent. Then, with an etching needle, or other agent, write the words to be etched: then make a solution of fifteen grains of chromic acid in eighty parts of hot water, add fifteen to twenty parts of sulphuric acid, and pour this over the plate or apply it with a pencil. As soon as it begins to act, a deposit of red chromate of silver will form. Examine the plate from time to time, rinsing off with flowing water, by holding under the tap for a moment, and applying fresh acid each time, until the etching is sufficiently deep. The chromic acid solution, unlike nitric and hydrochloric acid, does not have a tendency to spread or corrode under the protecting layer, and if care be taken, will leave a very fair etching.

RUSSIA permits all machines used in connection with the mining and reduction of gold ores to enter without the payment of duty. The Russian Minister of Finance has prepared a list of machines which, under this decision, is imported duty free. Machines used in gold washing, as pumps, water pipes, machines for the hydraulic treatment of gold, hydraulic pumps, dredges, amalgamators, etc., for the treatment of gold-bearing sands, machinery for the treatment of gold ores for the extraction of gold by the wet process, all kinds of furnaces, cyanide and chlorination plants, dynamos for the electrolytic separation of gold from cyanide solutions and machinery used for mining in general. Among such machinery are included dredgers, drilling machines, transporting apparatus, water pumping machinery, ventilators, and all kinds of mining apparatus.

COMPRESSED AIR can be transmitted with a smaller loss of useful effect when the pressure is high than when it is low; where equal weights of compressed air are transmitted through pipes of equal diameters, the resistance due to the transmission of the fluid varies inversely as the density. When the absolute pressure of air is doubled, the resistance due to its transmission is halved. High pressure steam, as well as air and other gases, are all subject to the same laws of resistance when in motion. The transmission of electric energy is also subject to the same laws of resistance as gases. When a powerful electric current is transmitted through an electric conductor, if it be desired to reduce the resistance, the voltage or electric pressure is increased; as the higher the voltage the lower the resistance, and, conversely, the higher the amperage or electric quantity the greater the resistance. A statement that includes electrical transmission and the transmission of fluids may thus be made: The resistances vary inversely as the pressures, and directly as the quantities.

A REMARKABLE occurrence of crystallization of minerals is found in the old Etta tin mine in the Harney Peak region of South Dakota. The hill rises—a conical mass of granite—in a formation of mica schist. The granitic mass is in the form of a lens, being at the center more than 100 feet wide, in length several hundred feet. In this mass of rock the minerals have a rudely concentric arrangement. In the outer layers occurs a development of crystallization, masses of feldspar and greisen, in which are crystals of spodumene from 12 inches to several feet in diameter and 10 to 50 feet in length. As exposed in a large open cut on the west side of the hill, these crystals remind one of great timbers which have fallen with the debris in a caved mine. The spodumene crystals are inter-penetrated with hexagonal crystals of tourmaline, apatite and other minerals. There are also crystals of black tourmaline of every size, from slender needle-like prisms to those over a foot in diameter having three curved sides. Masses of bluish-white and rose-colored quartz also occur nearer the nucleus of the great dyke. The cassiterite is found in the feldspar, greisen and quartz. Wolframite, columbite and tantalite also are found in this hill. This exceptionally coarse crystallization of minerals is common throughout the region, but nowhere on so great a scale as at the Etta mine.

A MEETING of the executive committee of the California State Miners' Association was held on the 21st inst. at San Francisco to take action relative to certain proposed mining legislation. The Association will ask the repeal of that portion of the State law requiring prospectors to record their preliminary notice of location. A committee was appointed by the president to visit the State capitol for the purpose of endeavoring to secure a liberal appropriation to give California mines proper representation at the Paris Exposition. In response to the invitation of the Association to the American Institute of Mining Engineers to hold their next meeting (probably in October) in San Francisco, a telegram from R. W. Raymond, secretary of the Institute, was read, announcing informally that the invitation would be accepted by the council at its next meeting. This will be the first meeting the A. I. M. E has ever held west of the Rocky mountains.

Les Mondes thus describes a process for metallizing wood: The wood is immersed for three or four days, according to its permeability, in a solution of caustic lime, at a temperature of from 75 to 90° C. From there it is placed at once in a bath of calcium hydrosulphate, to which, after twenty-four to twenty-six hours, a concentrated solution of sulphur and caustic potash is added. This bath lasts about forty-eight hours, at 35° to 50°. Finally, the wood is treated for thirty to fifty hours to a bath of acetate of lead, also at 35° to 50° It will be seen that the process requires considerable time, but the result is surprising. After having been dried at a moderate temperature, the wood thus prepared shows, when polished, a brilliant metallic luster. This luster can be heightened still more by rubbing the surface with a piece of lead, tin or zinc, and then polishing it with a glass or porcelain burnisher. The wood surface then assumes the appearance of a genuine metallic mirror, and is compact.

THERE is no more risk in the storage of calcic carbide than there is in storing any other inert material, provided it is packed dry and warm in hermetically sealed drums, so as to render it impossible for it to come in contact with water or moist air. The real risk is in the removal or redistribution of the material, as, after opening a drum, it may not be again properly closed, and if the drum be left in this condition in the moist air of an ill-ventilated cellar it is quite possible for a slow generation of gas to take place, and for an explosive mixture to be formed by its accumulation. All carbide stores should be thoroughly well ventilated and above ground, and when this is the case all danger is practically done away with. For the carriage of carbide it is important that not only should the drums be air-tight, but that they should be of sufficient strength to resist the rough usage incidental to the handling of a heavy product. Where tins are used, they should always be protected by an exterior wood case.

THE bill introduced in the California State Legislature by Curtin of Tuolumne, entitled "An Act for the better protection of persons employed in mines, providing for the appointment of an Inspector of Mines, and defining his duties and fixing his compensation," was referred to the Committee on Mines, Drainage and Debris. It provided for the appointment of an Inspector of Mines, "who shall visit every mine in the State, employing five men or more, at least once a year, and shall devote his entire attention to the duties of the office. His salary is to be $3500 a year, and his deputies, not to exceed five in number, will each receive $2100 for their services. Reasonable traveling expenses are also to be allowed. The inspector or deputy is to be admitted to the workings of any portion of any mine he may desire to examine, and shall note particularly the condition regarding the property that might affect the health or safety of employes. A complaint in writing, signed and verified by the oath of three or more persons, shall be sufficient demand on the inspector for an immediate examination and if found justified that portion of mine or machinery complained of must be at once put in good condition; the same rule also to apply to inefficient employes, the demonstration of whose inefficiency must result in dismissal within ten days." A proviso of the bill was that "neither inspector nor deputies shall in any manner disclose any information they might gain regarding the workings or character of rock in any mine. The inspector must file a bond for the faithful performance of his duties in the sum of $10,000 and each deputy $5000." The bill will not pass.

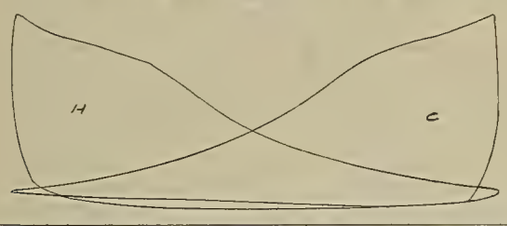
THE deposition of copper on iron may be accomplished either by dipping or by galvanoplastic methods. If iron be thrust into a solution of copper sulphate in very dilute sulphuric acid and left to remain for a short time, it is evenly covered with a thin but firmly adherent coating of pure copper. If allowed to remain longer the deposition of copper continues, but the plating becomes porous and less firmly adherent. This is, however, remedied, in the industries, by passing the plated surfaces between heavy steel rollers. From three to four ounces of the sulphate and a similar amount of the acid to the gallon of water are sufficient. Where the article is of a shape not easily compressible with the rollers, or where the surface has to stand much service, the electroplating process is in every way preferable. To plate in this manner, make a bath as follows: Into a suitable vessel put one part of crystallized acetate of copper and moisten it with sufficient water to make a paste. Add to this paste one part of sodium carbonate and five parts of water and stir until a light green precipitate (copper carbonate) is formed. Then in thirteen parts of water dissolve one part of sodium disulphite and mix the two liquids. In eighteen parts of water dissolve one part of potassium cyanide, and add the solution, under constant stirring, to the former mixture. The liquid should now be clear and colorless. If the potassium cyanide is, however, not up to full strength, it may have a dirty yellowish hue, to correct which more of the cyanide must be added. This had best be in the shape of a concentrated solution (though a small excess of the cyanide is rather a benefit), which must be added a little at a time and well stirred in, until the liquid is colorless. For very fine work the mixture should be filtered, but for ordinary work this is not necessary. The bath being now ready, an anode of pure copper, with a surface equal or nearly equal to that to be plated, is put into it, and the article to be plated is attached to the cathode and suspended in the bath so that it touches nothing. A current of medium intensity is requisite for good results in this process.

A Remarkable Hoisting Engine.

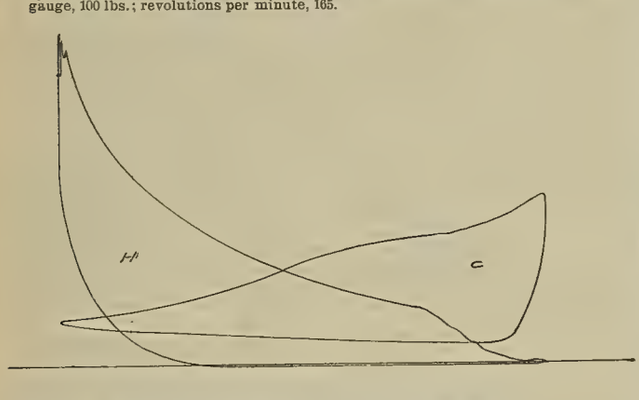
Written for the MINING AND SCIENTIFIC PRESS by GEO. S. BINCKLEY.

Hoisting engines are generally admitted to be the hardest worked of all the machines that are employed in mining operations, and, considering the severe duty that they are called upon to perform, it is surprising that the builders of these machines keep on designing them on the same lines, and with the same factors of safety, that are employed in the design of engines for ordinary duty where the power demanded, if not constant, is at least limited, and the changes from full load to no load is always comparatively gradual and the speed practically constant.

In the hoisting engine of the direct or first-motion type, the load, of course, varies at each trip from no load to full load, and, as will be seen from the diagrams herewith, the strains during the "plugging" of the engine while at full speed are enormously in excess of the ordinary working strains, and there is reason to believe that in most of the direct-acting hoisting engines in use these strains, if not neglected entirely, have been greatly underestimated by the designers.



NO. 1.—Diagram from double reel hoisting engine at Bell mine, Butte. Diameter of cylinder, 20 in.; stroke, 48 in.; date, Oct. 2, 1898; scale of spring, 60 lbs; boiler gauge, 100 lbs.; revolutions per minute, 165.



HEAD AND CRANK END TAKEN 3 SECONDS APART.

NO. 2.—Diagram from double reel hoisting engine at Bell mine, Butte. Diameter of cylinder, 20 in.; stroke, 48 in.; date, Oct., 9, 1898; scale of spring, 80 lbs.; boiler gauge, 100 lbs.; revolutions per minute, 165.

At the Bell mine, one of the properties of the Anaconda Copper Co., there is an engine in use which, in the matter of rotative speed and general performance, is probably one of the most remarkable engines in existence, and, although it has been in use for some years, twenty-four hours a day, there has been no accident due to the abnormal speed or sudden stopping of the machine, which, considering the fact that it is designed with no greater factors of safety than an ordinary Corliss engine, supposed to run at a speed of, say, seventy revolutions per minute, is remarkable and instructive, for it indicates how far the accepted factors of safety may be reduced and still leave a reasonable margin. In a good many cases a precedent like this is valuable, for when for any reason it becomes necessary to increase the amount of work, even for a short time, on a machine that is already installed, in the light of such a case as the one under discussion, much less uneasiness will be felt even when the amount of work done and the speed employed is far above that which would be allowed by any accepted formula.

The engine at the Bell mine is of the double-cylinder, direct-acting type, having cylinders 20″ x 48″, and is fitted with steam-actuated reverse gear, post brakes and clutches, the whole controlling gear being handled from the elevated platform that is occupied by the "runner." It has a Corliss valve gear of the Reynolds type, and is arranged so that the cut-off is regulated by the movement of the throttle lever, the cut-off coming into action when the throttle is full open, and allowing the valves to travel full stroke when the throttle is in any other position.

The post brakes were formerly applied by the direct application of steam pressure, but soon after the engine was erected the steam was accidentally shut off the whole engine while the cages were hanging in the shaft, with the result that both reels ran away and tore the reels, brakes and brake wheels all to pieces, luckily causing no loss of life.

The brake engines were then remodeled to the gravity system, in which the brakes are applied by heavy weights, and relieved by lifting the weights with the brake engines—this being a perfect safeguard against the repetition of such an accident and the method now generally used in connection with steam-actuated brakes.

The clutches are of a peculiar type, steam actuated, and having multiple jaws of steel, so arranged that the clutch may be thrown in at any position, by the movement of the reel through a very small angle. It is a rather complicated, but very satisfactory, arrangement, and as it is positive, it is somewhat more desirable on the score of safety than a friction clutch, even of the most approved kind. The reels are about 11 feet in diameter and will carry about 2000 feet of 4½″ flat rope. Double-deck cages are used, and each car carries a ton of ore of the ordinary grade, the weight of the car being about 950 pounds, and the two decks of the cages weigh about 4500 pounds, making the total load, exclusive of the rope, 10,400 pounds. This engine was designed by Hermann Unziker of Chicago, and was exhibited at the World's Fair at Chicago and afterwards sold to the Anaconda Co.

To fully understand the performance of this engine, it is well to bear in mind the wonderful skill of the "runners," for it is only by their marvelous control of the flying machine that such work can be accomplished. It is a pleasure to watch these men at the throttle, as they instantly interpret the complicated signals, and, with an incredible rapidity and exactitude, drop the cage from one level to another, setting it on the station chairs as easily as a passenger elevator, first the bottom and then the top deck, then, when the bell is given to hoist, starting promptly but gently, yet having the throttle full open before the engine has made two revolutions—waiting then until the engine has almost reached full speed, which occurs in a few revolutions, and then throwing in the cut-off, which is set for the maximum speed of the machine under full load. Then, while it seems to the observer that the engine is running away, such is the speed, the "runner" suddenly throws over his reversing lever, and the engine is "plugged," acting now as an air compressor, drawing in air through the exhaust ports and forcing it back into the steam pipes to the boiler. It is at this stage of the trip that the strains are abnormally heavy on the whole machine, as will be seen by reference to diagram No. 2, which was taken at a speed of about 165 revolutions per minute, with the cages running counterbalanced in the shaft at a speed of somewhat more than a mile a minute.

A rotative speed of 165 per minute, giving a piston speed of 1320 feet, would be sufficiently remarkable in an engine built with special reference to the conditions, but when it is considered that this engine is not built any heavier than the one that is accorded a maximum speed of about 80 revolutions, it becomes an instructive example of what may be done in the way of speed with an ordinary engine, when well built and erected. The fact must also be considered that in the case of a mill engine there is no "plugging," consequently an engine of 4-foot stroke, running at a speed of 165 per minute, would be well within the limits of safety when the performance of this engine, which has run under these severe conditions for years, is taken as an example. Another notable feature in the performance of the machine is the fact that the Corliss valve gear acts perfectly at this high speed, although it is not of any special type, and the dash-pots, hooks, etc., are not specially proportioned for extraordinary work. As will be seen by reference to diagram No. 1, the steam is somewhat wire-drawn during admission, and the back pressure is excessive, owing, in the first case, to the fact that the ports are not proportioned to the piston speed, and that the pipes are rather small, and, in the second case, the same remarks will apply, with the added disadvantage that the exhaust pipe is not very short, has several elbows and has to exhaust through a heater that is not of adequate size.

Both of the cards shown were taken at a speed of about 165 revolutions per minute, as near as could be ascertained without an instrument, this speed, of course, being maintained for but a small fraction of a minute, for the average hoisting speed of the cages in the shaft, from the 1600 level to the top, including stopping and starting, is over 45 feet per second. This is an almost incredible speed, especially when it is considered that the shaft is very crooked, owing to the bad character of the ground passed through, and the fact that it is continually moving. In connection with the crookedness of the shaft, it is interesting to note that more accidents occur when running at a low speed than when the speed of the cage is high, it evidently passing the kinks and tight places better the higher the speed. Wrecks in the shaft are rather frequent, but are rarely the cause of loss of life, although the speed at which men are handled in some of the shafts takes the breath away from anyone unused to this mode of travel and makes one wish for "dry land."

It will probably be considered by engineers who see these cards that an unjustifiable abuse of the engine is practiced, but it must be borne in mind by designers of this class of machinery that the conditions to be met are not determined by the limitations of the machine, but by the requirements of the mine upon which the machine is to be used, and that, if it is to be a success, the designer must not expect that a set of conditions to suit the ordinary engine will be provided by the mine, but he should ascertain accurately the conditions under which the engine will have to operate, and make his machine conform to them, even at the expense of his most cherished ideals of proportion, and in defiance of his most respected authorities. The writer ventures the opinion that if the designer of the machine described had fully realized the conditions under which it would have to work, he would never have ventured to use the proportions that exist in it now—no sane engineer would have done so, the conditions being fully understood—yet the fact that it has been successful is highly instructive, and merely emphasizes the fact that the conditions are not generally understood by the designer, and that it is more by good luck than calculation that the engines hold together. It will be seen from diagram No. 2 that when the engine is "plugged," the pressure reaches 160 pounds per square inch at the end of the stroke—a pressure that the designer certainly never intended to come on the cylinder. The practice of "plugging," however reprehensible it may be from the standpoint of the designer, is, however, one of the necessary conditions for rapid work, and a condition that must be met by the designer, whether he like it or not, if he wishes a consistent machine and one that will have as high a factor of safety as ordinary practice requires. The average mine superintendent requires that his hoist shall be able to take out the whole amount of the ore that his mine will produce, in a few hours each day, the rest of the time being taken up with the handling of timbers, waste and men, and a hoist that would be powerful enough to take out the ore in a short time, running at the ordinary speeds for a stationary engine of the same size, would be ridiculously out of proportion to the work of lowering men and timbers, and would be cumbersome and wasteful into the bargain, not to mention the extra expense in first cost and maintenance. The small appreciation that many designers have of the conditions under which these machines work is strikingly illustrated in some of the engines in use by the Anaconda Co. The builders have used their standard design of Corliss engine; but although the engines are all fitted with reversing gear, all of this make—in fact, all of the Corliss hoisting engines—are provided with a regulation hook-rod from the rocker to the wrist-plate! This, while harmless in itself, simply goes to show the blind adherence to tradition, so evident, though many other requirements are far more important as regards the safety and efficiency of the machines.

The little engine described above, although one of the smallest on the property, is certainly one of the most efficient and satisfactory engines that have ever come under the writer's observation, and although, as pointed out, the conditions are really normal, and the design of the engine does not strictly meet them, great credit is due the designer and builders, for the machine is an excellent example of good workmanship, handles with great ease, and has an unexceptional record for work performed. It cannot be denied that it exceeds the ordinary limits of safety, but the result is creditable and highly interesting and instructive to the engineer, for it indicates the lines upon which the design of this class of engines can be materially improved and rendered consistent with the work to be performed.

The performance of many other engines in use in Butte would be considered remarkable, but, in the writer's opinion, the instance given is the most striking and deserves the attention of engineers interested in the correction of the defects that commonly exist in this class of machinery. It is the writer's opinion that in engines of 48″ stroke there is no good reason that the high rotative speeds instanced above should not be employed in hoisting, as the advantages of a reel of small diameter are great when repair work, sinking and timbering is done with the assistance of the main engine, as the small reel allows of much easier handling, and, in addition to the lower first cost of the small engine, its economy in operation running at a high speed, is far superior to the large engine with slow speed, and the loss of steam by radiation from the jackets, and while handling, is correspondingly reduced. For depths up to 2000 feet, where double-deck cages are used, or an equivalent load is raised with skips instead of cages, an engine 20″ x 48″ is plenty large enough for the work, and if it is designed to meet severe conditions, and with sufficiently large port areas, there is no reason why an average rope speed of 45 feet per second should not be attained with a correspondingly high rotative speed of the engine, and a very high

economy in operation. In Butte maximum rope speeds of nearly 6000 feet per minute are successfully employed, and there are few accidents from this cause. The whole problem would be greatly simplified if it were convenient to use round ropes and drums of small diameter, for in that case very deep mining could be carried on with engines of small size and high efficiency. Several devices for overcoming the necessity of very long drums have been suggested, but so far the problem is unsolved, for a drum of sufficient capacity, if the diameter be small, becomes entirely too long to lead well over the sheaves.

Although the subject is a difficult one, there seems to be more room for improvement in hoisting machinery and methods than in any other class of mining machinery, and the increasing demand for more efficient machinery in every branch of mining must result sooner or later in the development of a new system, or, at least, important modifications of the present system, of hoisting and handling ore.

The Genesis of Petroleum and Asphaltum in California.

NUMBER IV.

Written for the MINING AND SCIENTIFIC PRESS by A. S. COOPER.

Fossil bitumens are found in California in the unaltered rocks which exist in a strip of land adjoining the coast of the Pacific ocean, being from sixty to seventy miles wide and extending from Del Norte county on the north to San Diego county on the south, a distance exceeding 700 miles and covering an area exceeding 40,000 square miles.

These fossil bitumens occur on the surface in the form of gas, oil and tar springs and bituminized shale and sandstone.

In the succeeding pages the phenomena attending bituminous deposits in general will be given, and then descriptions of different deposits, showing that these phenomena are applicable to all deposits.

Anticlines, synclines, monoclines, centroclines and quaquaversals, and also faults, exert a great influence in the accumulations of gas, petroleum oil and water. Especially is this true in California, where the dips and undulations along the strike of the anticline are exposed and well defined.

Although a description of the different inclinations and curvatures of strata would seem elemental, a thorough knowledge of the effect of these inclinations are necessary for an understanding of the laws governing the accumulations of bitumen in California. In the Eastern States the slopes of the domes frequently do not exceed 20 feet to a mile, whereas in California the strata stand at a very steep angle with the horizon, frequently being overturned.

When a group of strata is bent into a curve like a saddle, with its convexity turned towards the earth, it is called an anticlinal curve. Such a condition of strata is shown in Fig. 1 above the word anticline. A synclinal curve is exactly the opposite of an anticlinal curve. When the strata is folded or curved so as to form a trough, the concave side of which is turned from the earth, it is called a synclinal curve. This is shown in Fig. 1 above the word syncline. In both anticlines and synclines the line in each bed along which the change in the direction of the dip takes place is called the anticlinal or synclinal axis of that bed, and the planes containing all the axis of an anticlinal ridge or a cynclinal trough are called axis planes. The axis plane usually approaches verticality. Anticlines and synclines frequently nose out, or coalesce.

When an anticline undulates along the line of its axis dome-like elevations occur, from the summits of which the beds dip away in every direction. In this this case the strata is said to have a quaquaversal dip. An anticline is an elongated dome.

A quaquaversal, or dome, is a nest, usually of a great number, of different strata composing numerous overlying, gigantic, inverted funnels, the strata of the formation forming the sides of these rock funnels, all of which tend to guide and convey the ascending gas and oil to the apex of the dome.

When a syncline undulates along the line of its axis basin shaped depressions occur, towards the bottom of which the beds dip from all sides. This is called a centroclinal dip. A syncline is an elongated basin.

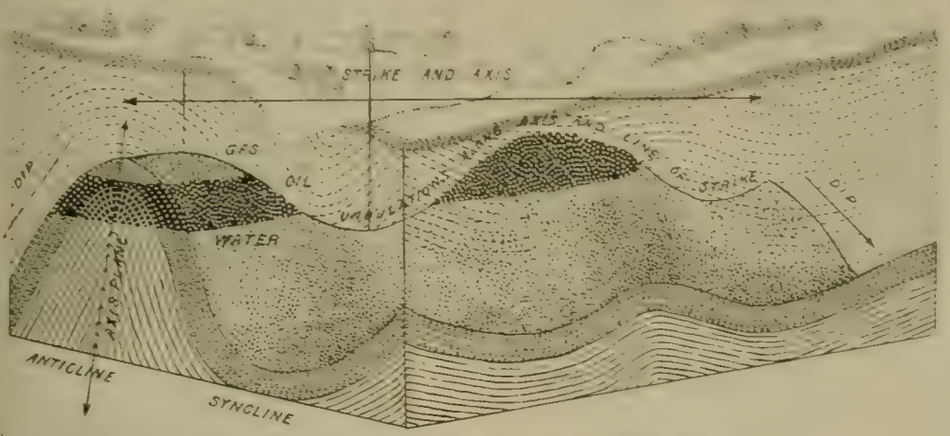


FIG. 1.—PLANO-SECTION SHOWING INCLINATIONS.

A fault or dislocation is a fissure or crack in the crust of the earth, accompanied by the elevation of the mass upon one side of the fault, while the other side remains stationary or sinks down. Anticlines and synclines are often truncated by faults, and may be so faulted as to form the segments of a sphere or cone. If an oil-bearing bed ascending to the north be interrupted by an east-and-west fault, the further ascent of the oil northwards will be arrested, and then an abundant supply of oil may be obtained by boring on the south side of the fault, while, for a considerable distance to the north, water will occupy the formation to the exclusion of the oil. This is more apt to be the case where the throw of the fault is sufficient, so that the edges of the porous strata are covered by impervious strata. Selvage frequently occupies the line of faults generally caused by the movement of the two sides of the fault on each other, which have ground up the materials of the rock, forming a sheet of matter impervious to the flow of oil or water, or the faults may be filled up with mineral matter of various kinds, which are also impervious to oil or water.

FIG. 2.—BITUMENIZED SAND FORMING AN ANTICLINE.

When a formation contains permanent water, the accumulation of petroleum oil will be found near the upper part of the dome, as is shown in the plane section, Fig. 1. The oil floats on the surface of the water, and if natural gas is present it will be found above the oil. These three substances arrange themselves according to their specific gravity, the lightest on top.

Fig. 2 is a view of an anticline. The camera was pointed in the direction of its strike. The white line represents the plane of bedding, which was once horizontal, but is now curved in the form of an arch.

(To be Continued.)

Experiences of a Working Miner.

Written for the MINING AND SCIENTIFIC PRESS.

In my last letter I promised to tell you about some peculiarities I have seen in mine timbering, and shall do so, but before entering upon that subject I want to say something more regarding transportation and handling of ores. I think one of the worst cases that has ever come under my observation was that of the C. I. Co. They shipped their ores, and while necessarily an expensive proposition, it was made much more so by the manner of handling the ores. The mines were situated half a mile or more (according to the location of the several workings) from the ocean. The ore was delivered at the mouths of the several tunnels, where it was sacked and stacked up in large piles. At some convenient time these sacks of ore were placed in a chute and went sliding down the mountain side with accelerating velocity, landing at the bottom of the slide like so many cannon balls. Often sacks would burst and required resewing. This might have been prevented by flattening the lower end of the chute, which would have landed the sacks at a much lessened rate of speed and without material damage to the sacks. From the bottom of the slide the sacks were "packed" by burros to the shore, and here they were again piled in neat stacks until some day a vessel hove in sight and anchored a hundred yards off shore. A scow was then employed to transfer the ore to the vessel. A sufficiently good pier could have been built at small cost and soon paid for itself. The vessel then sailed away to a foreign port and unloaded the ore on the docks. Flat cars could have been obtained and the ore placed immediately upon them. When the ore was eventually placed on the railway flats it was taken several miles to the reduction works (a small concern leased by the company), and here it was again piled up on the ground as neatly as before, with aisles between for tracks. Here, again, a saving might have been made by unloading from the flat cars onto a platform of equal height, having trap doors at regular intervals, so that small mine cars might be run underneath and the ore dumped into the cars before sending it into the mill—for it was not a reduction works at all, but called so out of courtesy. From the piles of sacks on the ground two men lifted three sacks onto a small trolley car (or flat), pushed the trolley from 100 to 300 feet to a small platform scale, where each sack was carefully weighed—why I do not know, as after weighing fifty sacks they could have found an average sufficiently close for all purposes. Having weighed the sack of ore, the two men lifted it bodily, cut the string, and dumped the ore into the car. When the car was filled it was trammed into the mill, run onto an elevator and slowly hoisted to the ore floor and dumped. I must not forget to mention that at this mill they had one of those elevated rock breakers referred to in my last letter—but, then, this might have been expected. Perhaps the worst feature of the whole business was that they were unable to save much above 50% of the value in the ore. This mine didn't pay. Whether it could have been made to pay under judicious and experienced management or not I cannot say, but I am sure I can see several "leaks" in the profits, and so, doubtless, can you.

L—— owned a large and profitable mine and he ran it on a broad gauge basis—so he thought—but I know of other mines that are better handled. The S—— mine had a great reputation, and it was a well-earned reputation, too, but L—— had some queer ideas about how his mine should be worked, and also some equally queer ideas as to how it should be timbered; or, perhaps, he didn't have any ideas at all on these subjects. But if not, then some one else about the place conceived these remarkable notions and L—— sanctioned them. The vein was large and the walls firm and solid—particularly the hanging wall—and a sort of "square-set" system of timbering was invented, and it was in this square-set that one of the remarkable notions showed itself. The timbers were framed in such a manner that the caps did not meet on top of the posts; nor did the tenons of the posts fill the space. Sometimes this space was filled with a block and very often it was not. One day I asked why the timbers were not framed in such a manner as to form a most rigid support to the ground until filling could be run in. The bit of information I got in answer to this question convinced me that argument would be useless. "Don't you know," said L——, "that it is proper to frame the timbers in such a way as to let them 'give' a little?" "What for?" I asked. "Why, to keep from crushing the timbers," replied L——. The only reply I could make was: "Don't you know that in one of your wide stopes the timber 'giving,' as you call it, say 2 inches on each set, will allow the hanging wall to settle over 2 feet (I have seen the hanging wall standing in great slabs, parted from the main hanging country, 5 feet and more in this very mine), and that once started it is not only very dangerous and more difficult to hold, but also will eventually make it far more expensive to continue mining operations, and that you will lose lots of ore?" "No, he replied, "I don't know anything of the sort, and I won't."

But he did, just the same.

MINER.

Temperature of Battery Water, Etc.

To THE EDITOR:—I have noticed in recent issues a number of articles on the temperature of battery water, and also on amalgamation and the general treatment of plates, etc.

Having had some years' experience in this work, the articles mentioned have proved of much interest to me.

I have experimented to some extent with the temperature of battery water, having had a range of from 40° to 80°, and I have found that better results were obtained with the temperature from 60° to 70°. With the lower temperature there was a noticeable tendency of the mercury to flour, and our loss of mercury during the use of cold water was higher than with the warm water, as was also the tailings. With warm water a much smaller quantity of mercury is required to amalgamate the gold, heat seemingly aiding the formation of the gold-mercury alloy and decidedly aiding concentration. The warm water softens the rubber belts of the concentrator and the concentrates show less tendency to work down toward the tail of the machine, apparently clinging to the belts. With warm water I found it very difficult to get the battery men to curtail the use of mercury to meet the increase in temperature, as at first they were inclined to use too much mercury and cause a dripping plate; but this difficulty was soon overcome and our results were very satisfactory indeed.

I quite agree that the use of acids on silver-plated plates is the worst practice possible. A solution of caustic potash or a very weak solution of cyanide should be used, and the latter very sparingly.

One of your correspondents condemns the lengthwise sweeping of the plates. I have found, in some cases, that in cross-brushing there is an accumulation of very fine sulphides, which prevents the proper contact of the gold and amalgam. The contention may be that these were a very high grade sulphuret, but I will say that a very careful sizing and assaying of the concentrates produced at this time showed the fine sulphurets to be by far the lowest grade of sulphuret produced.

I also found that as sparing a use as conditions would admit of water, both in the batteries and on the plates, gave the best results; and in the use of mercury to feed as little as possible in the batteries, using the bulk of it on the plates.

I fully realize that there is a difference of conditions in different localities, and that no hard and fast rules will govern the subject.

I see much has been said regarding screens. I have been using them—punched tin screens—where we have been crushing a little over three tons to the stamp. Considerable quantities of chips and sticks come up from the mine, which very much shortens the life of the screens. In the use of 63 screens, unburned, the average life was 12½ days. The average life of the same number of screens, the tin having been burned off, was 15 7 days. The longest life of any individual screen was 45 days. Of course, the holes were worn quite large, but I wished to see how long it would last. The average life was considerably lessened, as the sticks would often punch a screen out in a day or so, and a more proper average life would be about three weeks. H. S. C.

Greenwood, El Dorado Co., Cal.

Electrolytic Production of Zinc in 1898.

The chief event of 1898 in the electrolytic zinc industry has been the definite abandonment of the Ashcroft zinc extraction process, after lengthy trials at Newcastle, New South Wales. The failure of the process is attributed by the inventor to three causes: (1) diminished metal value of the ore sent for treatment; (2) difficulties due to the accumulation of manganese; (3) lack of necessary financial support. The failure of the process has obliged the Sulphide Corporation, which purchased the patents, to write £137,500 off its capital account, and has led to much mutual recrimination. Four wet extraction processes are still in operation, but only two of these are working upon a commercial basis. The Hœpfner process is operated at Winnington, in Cheshire, and at Fuerfurth, Germany; in 1897 1200 tons zinc were produced by this process at these works. The Dieffenbach process is worked at Duisburg, in Germany, and is stated to be producing about 90 tons zinc monthly. Both of these processes utilize zinc chloride solutions as the electrolyte, and it is questionable whether they would prove profitable in the absence of the chlorine liberated at the anode. The Cowper-Coles extraction process is in experimental operation at Hayle, in Cornwall. At Lipine, in Silesia, the Nahnsen process is reported to be still in use.

Many believe that the solution of the problem of zinc recovery from refractory sulphide ores will be solved by a dry or fusion process, belief shared by the writer; and on this account the Swinburne sulphide ore process is of exceptional interest. The trials to be made during the present year with this process will show whether the expectations formed by its inventor as regards its practicability and economy are justified. Another fusion process—the Fry process—has emerged from its experimental stage during 1898, and works are now building at Manchester on a very large scale for industrial operation of this process. It is not, however, an electrometallurgical one, and it is only mentioned because its operation will probably cause a serious fall in the price of zinc, and leave but slight margin for profits to the wet-extraction processes.

In the electro-galvanizing industry there is not much to report. The Cowper-Coles process is employed by several firms in this country; the Greenwood process is also in operation. Abroad, the Alexander process and the Richter process are used. There are no figures available from which the output of galvanized iron work by these various firms can be ascertained.—J. B. C. Kershaw in Electrical Review.

Cheap Mining in Australia.

Some of the large low-grade gold mines of Victoria, Australia, are making notable records for cheap mining and milling. The London *Mining Journal* says:

Quartz mining in Victoria is now being carried on in a very economical manner. The methods of mining the stone underground and bringing it to the surface have been reduced to a science, and it is probably nowhere more economically done than in Victoria. There is much room for improvement, though, in the method of milling the ore.

The half-yearly statements of several of the public companies, recently issued, give interesting details, and show what can be done by systematic and economical management. Anything over 3 dwts. to the ton would be regarded as comparatively rich. The Central Ellesmere crushed for the half-year 6900 tons for 911 ounces 1 dwt., an average of 2 dwts. 15 grains per ton. This gave a profit on actual working expenses of £1030 17s. 1d. The cost of treating the stone had been only 6s. 9d. per ton, against 7s. 0¾d. the previous half-year. The Thomas United, though their stone averaged under 2 dwts. per ton, from 4147 tons came out with a profit for the half-year of £510. This company has acquired a good winding and crushing plant, and opened up the mine to a depth of 130 feet without making calls.

More remarkable figures are shown by the Stewart's Extended, which company has no battery, and has to cart and pay for crushing. Its average was 2 dwts. 7.2 grains per ton, and on a yield of 219 ounces 19 dwts. 11 grains from 2778 tons, a profit of £34 3s. 7d. was obtained. The Stewart's United, which in December declared a dividend absorbing £300, had an average of less than 2 dwts. per ton for the half-year's work, 4881 tons being treated for 476½ ounces. This company has paid nine dividends on crushing stuff averaging all through considerably under 3 dwts. per ton.

When we consider that the mills at which the stone is crushed are far from being up to date, and contain neither rock breakers nor self-feeders, it must be admitted that the work is carried out in a very economical manner.

An Arizona Necessity.

To an observant and experienced mining man who visits the various mining plants of the country, nothing presents itself so forcibly as the general absence of complete concentrating attachments. Go even to the latest introduced enterprises and the management seem content with the most limited devices for saving the plate waste and base values from the ores. It is too bad that this is true, and yet it is practically a universal fact in this country, and it is practice that is readily accounted for. The seductive enchantment of Yavapai's rich pockets of free ore has extended so potent an influence in shaping local mining opinion that it is proving a slow and difficult process to bring our miners to a realization of the extent that this Territory's mining future depends upon the successful saving of values in its ores that cannot be secured by ordinary amalgamating processes. At Ward, Colorado, a base pyrite ore is extracted, hauled by a wagon to a mill and concentrated at a total expense of $3 25 to $3 35 per ton. This ore, exclusively a concentrating proposition, averages a saving of $4 per ton, leaving a net profit to the operators of about 70 cents per ton. Of course such a proposition as this must be based upon large ore bodies and cheap mining, but Arizona has as good a claim as any section to the probability of such mineral bodies. I wish to insist and to "harp" upon this theme—this neglect of the base and unplatable values in the ores of this country. It is now generally conceded that the most free of local ores carry a per cent of gold that quicksilver will not retain, while much of the mineral of our veins carry high per cents of the yellow metal in such form. Still our mill men, almost without an exception, seem satisfied that what two or three vanners will not catch is not worth saving. This is a bad mistake and should be corrected.—W. E. Mendenhall in the Prescott Courier.

Co-operation in Mining.

Where the system of co-operation has been given a fair trial it has proved a success. Many a miner works underground for six months in the year to save up enough to prospect in the hills during the summer season. Some are not fortunate enough to secure work during the winter months and to defray their expenses sell their claims for very little.

Mining is a branch of business in which co-operation would be advantageous. Instead of scattering in all directions, it would be better for a few practical men to get together, pick out the most promising claim on their list and co-operate in working it for all it is worth. At present they often sell their claims for a few dollars, the property passes into the hands of another, who accordingly turns it over for four or five times the price paid, and so on until finally it comes into the possession of some syndicate that reaps the profits that might go into the pockets of the original locator and would be his if he but conducted his business on the co-operative plan. Instead of selling undeveloped properties for a mere trifle he might, on this plan, develop them and get more. Such a system would also be beneficial to the country at large and tend to its speedy development.

One developed property in a district does more to establish a reputation than a score of prospects, however good they may be. It does not require more capital than the ordinary miner or prospector generally possesses to go into a scheme of this sort. When men show their faith in a property by devoting all their energies to its development they naturally gain the confidence of capital. Practical men will know a good thing when they see it, and if it be their own they will work it more energetically and economically than if it were in the hands of some corporation. Sufficient work can generally be done by hand and a cheap plant installed to demonstrate the value of a property before heavy and expensive machinery need be introduced. Mining is essentially a business adapted to the co-operative plan. A dozen men or so, bound by ties of self-interest, if nothing else, could accomplish much in this way. The idea is worthy of consideration.

Iron and Steel Market.

A rumor extensively circulated is to the effect that the iron and steel market is dangerously affected by the scarcity of material.

One prominent dealer says: "While it is true that the price of iron has risen, there is enough iron ore in this country to supply the market, and more, too. The fact that there is a delay in the delivery of special orders does not imply a lack of crude material. It simply means that the capacity for putting out the finished article is inadequate to the demand. Another reason is the fact that the manufacture of iron has not been upon a paying basis. The laborer's wage has been too low, and prices correspondingly so. There have been dull times in the iron business, as in everything else, and then the prices dropped and left the manufacturer between the horns of the dilemma. One proposition was to close his works for the time being and throw thousands of men out of employment, cut off his profits, and yet be under the expense of keeping up his business until times grow better. Afterwards he would have to break in a new force of men. The alternative which was more logical, and at the same time a more humanitarian view, was to run his business at a loss and use foreign countries for a dumping ground. In most cases this was done, and thus prices were cut to pieces. Now, when home consumption is sufficient to consume the output, wages will regain a normal standard and iron will naturally increase in price. The foreign market will suffer and exportation of iron and steel will be cut in two, but the European buyer, and not the American manufacturer, will suffer by the changed conditions.'

A Great Many Say So.

The MINING AND SCIENTIFIC PRESS of California is the leading mining paper of the world.—Creede, Colo., Candle, Feb. 18th, '99.

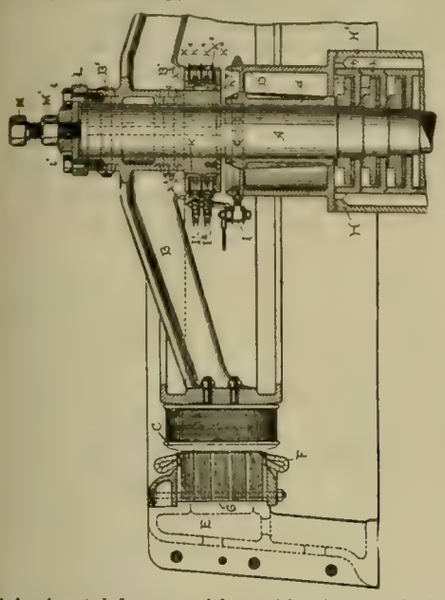
EXCHANGES report the death of several miners in various parts of the country the past week from falling into shafts, in most cases, from stations underground. While miners, as a class, become careless by constant exposure to the dangers of their business, it would seem that many such accidents as above referred to could be prevented by proper precautions on the part of the mine owners by the construction of guards about the shafts at stations.

Latest Mining and Metallurgical Patents.

Patents Issued February 14, 1899.

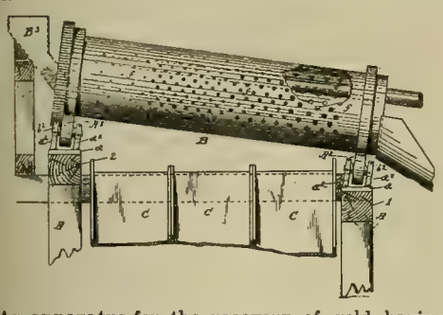
Specially Prepared for the MINING AND SCIENTIFIC PRESS.

DYNAMO ELECTRICAL MACHINE.—No. 619,296; S. S. Forster, Schenectady, N. Y.



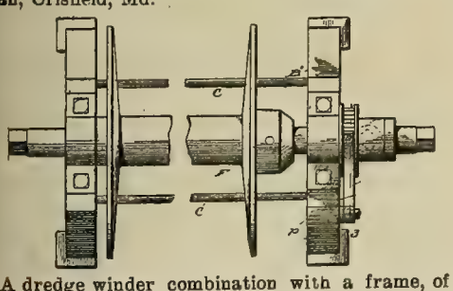
A horizontal dynamo with combination of split-hub spider, a collector fixed to one side of the spider with a space between the other side of the spider and the collector, means for securing the hub to a shaft, a supporting bearing, and means for adjusting the position of the spider without disturbing the collector when for any reason, as by wear of the bearing, the spider is out of its proper position.

ROTARY GRIZZLY OR SEPARATOR.—No. 619,341; Robt. H. Postlethwaite, San Francisco, Cal., assignor to the Risdon Iron Works, San Francisco, Cal.



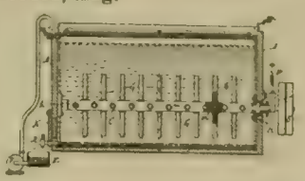
An apparatus for the recovery of gold, having a combination of a rotary cylindrical grizzly of approximately uniform diameter throughout its length, the perforations therein being arranged in sections and increased in size from the feed end toward the discharge end, with separating tables below the grizzly, means for rotating the grizzly and a tapering water supply pipe extending into the grizzly with the small end nearest the feed end of the grizzly, and provided with outlet openings so arranged that the outlet of water will be proportioned to the discharge of material from the various sections of the grizzly.

DREDGE WINDER.—No. 619,591; Maddrix & Godman, Crisfield, Md.



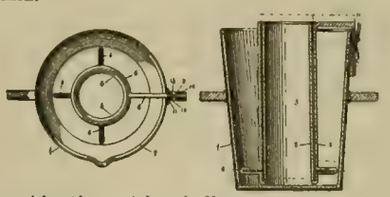
A dredge winder combination with a frame, of a winding shaft mounted in bearings to rotate and slide longitudinally, a winding spool or drum mounted loosely on the shaft and provided at one end with clutch teeth or lugs, a clutch head fixed to the shaft and adapted when the shaft is slid longitudinally to be engaged or disengaged from the teeth of the spool to hold the same rigidly in engagement with the shaft, a sleeve loosely mounted on said shaft adjacent to the clutch head and provided on its interior with spiral grooves and on its exterior with an annular series of ratchet teeth and circumferential limit flanges arranged at opposite sides thereof, a pin fixed to the shaft and having its opposite ends projecting into and adapted to traverse the grooves in the sleeves, and a pawl pivoted to the frame and engaging the ratchet teeth on the sleeve adapted to prevent backward rotation of the sleeve.

EXTRACTING GOLD FROM SLIMES.—No. 619,349; H. Riecken, London, Eng.



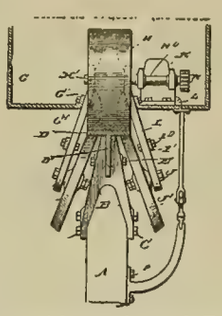
An electrolytic process of extracting precious metals from ores or slimes, consisting in agitating a mixture of the ores or slimes and an electrolyte in the presence of an anode, causing a stream of mercury to descend in a thin film over a metallic surface forming a cathode, passing a current through the pulp to the cathode and thereby amalgamating the precious metals and depositing them in an adherent layer upon the cathode, collecting the descending mercury and reconveying it to the top of the metallic surface.

FOUNDRY LADLE.—No. 619,431; D. W. Nash, Eastlake, Ala.



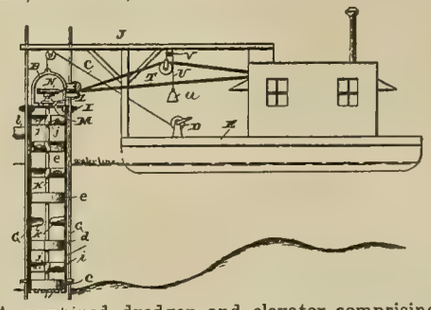
A combination with a ladle of a hollow bottomless cylinder placed therein and arranged to seat on the bottom of the ladle, the connecting arm attached to the head and having an apertured stem extending downwardly on the outside of the ladle, the eccentric cam operating in the aperture formed in the arm stem, the nut to clamp the cam.

AERIAL RAILWAY.—No. 619,536; Jno. Bond, Turlock, Cal.



A combination with an elevated T-rail, of a carriage comprising bearing plates carrying a roller to bear upon the upper surface of the T-rail, bevel rollers to bear against the under surface of the T-rail, the plates inclining laterally and downward, straddling the tops of the poles; a balloon or airship supported upon the carriage and carrying a motor, curved brackets on the sides of the poles, a line wire supported therefrom, and a trolley pole depending from the carriage and carrying a trolley wheel in contact with the wire.

DREDGER AND ELEVATOR.—No. 619,675; A. W. Cram, Haverhill, Mass.

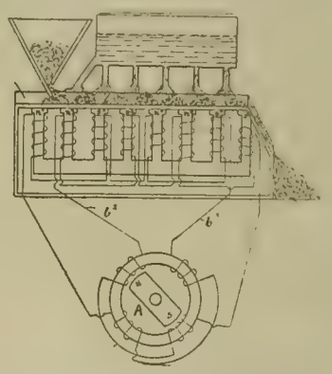


A combined dredger and elevator comprising a propeller tube, a centrally and longitudinally arranged shaft within the tube, a combined cutter and propeller secured to the lower end of the shaft within and at the lower end of the tube, a plurality of propellers attached to the shaft and concentrically arranged within the tube one above the other, and a plurality of oppositely inwardly extending blades attached to the tube and arranged between the propellers, and an operating mechanism. The elevator tube has an open lower end; the propeller blade has at the center of its lower side cutting blades *h*.

APPARATUS FOR PLACER MINING.—No. 619,647; G. Wetherby, Duluth, Minn.

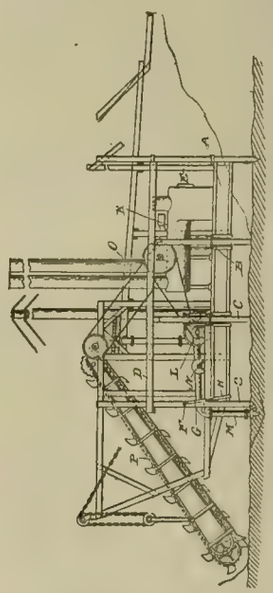
An apparatus for use in placer mining for loosening dirt or disintegrating hard or frozen earth by means of steam, the combination of a suitable steam supply and a conveyor or hose for delivering steam to the desired point, with a hose support consisting of a rod *d* having at each end thereof semicircular holders *e*, *e*, a forked leg *d'* and a sliding brace d^2 connecting said rod *d* and leg *d'*, and the extensible legs d^5, d^5.

APPARATUS FOR SEPARATING MAGNETIC MATERIALS.—No. 619,636; O. A. P. Trustedt, Stockholm, Sweden.



A magnetic separator with a combination of a series of electromagnets, a stationary non-magnetic covering on the magnet poles and a source of multiphase alternating currents of which the windings of each phase are connected to different magnets in the series.

DREDGING APPARATUS.—No. 619,901; A. McDougall, Duluth, Minn.



A mining apparatus with a scow *A* provided with adjustable legs or spuds *C*, having pins *F* passing through each with adjustable turnbuckles *G* thereon, the lower ends of which are connected to a strap *H*, secured to the scow.

IGNITER FOR GAS ENGINE.—No. 619,396; W. L. Crouch, New Brighton, Pa.

In a gas engine, the combination with the cylinder, of an ignition tube upon the exterior of the cylinder, a non-conducting cover inclosing the ignition tube and arranged to leave a space between the cover and tube, the cover being provided at or near its top with an opening, a removable cover adapted to close the opening, a strip or body of material capable of being heated to incandescence suspended within the ignition tube and a burner communicating with the space between the cover and ignition tube.

Some Notes on Alluvial Mining in New Zealand.

Written for the MINING AND SCIENTIFIC PRESS by JNO. W. GRAY.

According to the report of the Department of Mines for the year just past, the interest in alluvial mining continues unabated. The following notes are mainly taken from information given in the Government report and will probably be of interest to those in any way connected with this class of mining:

In the provinces of Otago and Southland claims are taken up not only on the rivers but on the terraces and flats adjacent, and also on the alluvial flats where depth of ground has hitherto been the obstacle to the ground being worked by older methods. Dredging is the popular method of mining and operations are being carried on in the swift-flowing streams such as the Clutha, Kawarua and Molyneux; also in the lesser rivers, smaller streams and old river deposits. The material is elevated from 25 to 30 feet in the rivers and from 6 to 30 feet in other places, requiring dredges of modified construction according to the peculiar conditions of the different localities.

It has been demonstrated that dredges can be successfully handled with very limited water supply. A large paddock is first excavated of sufficient dimensions to float the dredge. Operations are then begun on one side, the gravel being discharged behind the dredge by flume or an elevating conveyor. The fine gravel only is discharged without being elevated. If the water becomes thickened by continued use, as is generally the case, it is partially cleared by such small continuous or intermittent flow as is obtainable. A very moderate quantity of water is thus found able to keep the paddock water in a satisfactory condition for working purposes. The water is continuously used and such operations have proven successful. Prior to being worked land may present a level appearance. Afterwards, though not so level, it is left in such a state that it can be harrowed and sown to grass, no great permanent damage being done to the land and the streams are not polluted to any extent nor filled up as in ordinary sluicing.

The marked advantage claimed for the dredging operations as compared with sluicing is that it enables large quantities of material to be elevated and then deposited at a less cost than by any mechanical process now in use.

In the matter of dredging, however, the public is warned not to fall into the error that has sometimes attended quartz mining, namely, the construction and erection of costly machinery for the treatment of material, the quantity and value of which has not first been ascertained properly. Systematic preliminary prospecting is recommended, of so complete a nature as to fully establish the quantity and value of the material to be handled, as well as to determine the conditions of working, so that the machinery to be used can be properly designed for the work to be done.

The great area of river deposits in Otago and Southland, which are known to contain small quantities of gold, are thought to be worthy of careful prospecting, with every reason to expect the discovery of localities where the gold occurs in payable quantities and which will give promise of profitable dredging work.

A large number of dredges are said to be in more or less successful operation in the many localities where work is now being carried on. Complete returns of the gold won by these operations are, as is usually the case, not obtainable, as the owners in many instances are unwilling to have their yield of gold published. Partial reports, however, show that eighteen dredges yielded during the past year, ending March 31st, 1898, 10,909 ounces, an average of about 606 ounces each. The highest yield was that of the Clyde Co., operating at Alexandra, viz., 2224 ounces. Returns from the great majority of the dredges are not given. Improvements are constantly being made in dredge building and equipment, different engineers vieing with each other in producing more powerful and effective machinery. The following brief description of two new up-to-date dredges may not be out of place:

Magnetic Company's dredge—Length 109 feet, width of beam 25 feet 6 inches, depth 7 feet. The ladder is 75 feet long and is designed to dredge to a depth of 50 feet from the surface of water. The buckets are 5½ cubic feet capacity. The engine is one of Marshall's 16 H. P. compounds, and surface condensation is effected by water raised for gold-saving purposes. The winch is driven by a pair of horizontal engines fitted with reversing motion. The boiler is a Cornish multitubular; working pressure 150 pounds per square inch. The ladder is raised and lowered in the usual way from the winch. The buckets are put in motion by the tumbler driven by gears and rope drive from the engine. The material is delivered on a drop plate and thence into a perforated screen, the fine stuff falling through onto the gold-saving tables. The material is washed by perforated pipe running through the screen, and the tables are supplied with an additional supply by branch pipes. Water is supplied by a centrifugal pump, driven from engine by a belt. The coarse material is delivered directly into the current or elevated by a traveling conveyor. This dredge will be the largest afloat in the province of Otago.

Unity Company's dredge—Length 85 feet, width 26 feet 6 inches, ladder 60 feet, buckets 4½ cubic feet capacity. The engine is a 16 H. P. compound with surface condenser. Centrifugal pump and air pump are placed below deck. The winch is driven by worms and worm wheels, the power being supplied by a pair of vertical engines with reversing gear. The boiler is a Marshall's 20 H. P.; working pressure 140 pounds per square inch. The ladder is raised and lowered in the usual manner. The material is delivered from the buckets into a revolving screen, the fine stuff being distributed over a double set of tables leading each way from the center of the screen. The coarse material is elevated and dropped astern.

The coming year, it is said, will see important additions to the number and character of the dredges operating in the colony.

On the west coast dredging has not yet become so general or popular as in the provinces above mentioned. There are evidences, however, that many of the flats containing auriferous gravels will be so worked. In several localities small dredges are doing prospect work preliminary to larger operations.

The company operating on the Buller river is having a new, large and powerful dredge constructed, capable of handling 100 yards of material per hour. The work of this company is said to have given profitable results.

The success that has attended dredging in Otago, in places where no large stream is available, has proven the possibility of working large quantities of gravel with a limited water supply, and this fact has increased the interest in such operations in other localities where the conditions are similar.

In the ordinary work of hydraulic mining no special changes have taken place during the year. The Government has somewhat enlarged and repaired some of the more important water supply races, and is pursuing its plan of investigating the possibilities of water conservation and distribution for the benefit of the mining industry. The communities depending upon alluvial mining are as prosperous as usual, and the year generally has been a busy one.

As illustrating the operation of gravel elevating in the colony, some data relating to two of the most important plants may be given.

At the Blue Spur Cons., Otago, the following table shows the work done during the year 1897-98:

	Hours Sluicing.	*Cement, Cu. Yds.*	*Gold, Ozs.*	*Value per Cu. Yd. Gr.*	*d.*
No. 1 Division	2,636	70,177.6	1,085.7	7.43	14.68
No. 1A	571.5	10,001.2	24.7	1.19	2.34
No. 2	1,146.5	38,178.4	555.8	6.94	13.80
No. 2B	2,807.5	84,225.0	1,497.7	8.53	16.86
	7,161.5	202,522.2	3,163.9		

No. 1 elevator lifts 68 feet. No. 2B works in series 43 feet and 69 feet, making a total lift of 112 feet. No. 1A and No. 2 represent development and stripping. Total yield of gold was 3163 9 ounces, which at £3 19s per ounce = £12,497 8s. The cost of production was 50.15% of the gold won. The two main items of expense were labor and explosives. About 7500 pounds of roburite were used, and the cost per ounce of gold, for labor and explosives alone, was £1 8s 5½d.

At the Round Hill Co.'s property, Southland, extensive operations are carried on by elevating and sluicing. The banks average 40 feet in height with a slight depth of auriferous wash dirt lying upon sandy and hard clay bands constituting false bottoms, and on a main bottom of igneous formation. Elevators of 13 inch pipe are used, with patent oval seats 16″x 10″, having throats 3 feet high and 6 inches diameter. These, with a properly regulated water and dirt supply, are capable of lifting seventy tons per hour to a height of 50 feet. Air injectors are attached to cause a body of air to accompany and surround the water forced up the elevators, thus diminishing friction and otherwise aiding the work of lifting. The average number of Government heads to each elevator is 5.434, each head being equal to 1 cubic foot per second, and on each piping nozzle on face 3 63 heads.

The average gold recovery has been 1¾ grains per yard, valued at 3½ pence or about 7 cents per cubic yard. Details of cost of operation are not given, but it is said that the company makes a fair profit with the yield as above given.

A Montana Miner's Tools.

In Anaconda, Jas. Bray has seven tools made by himself, three being pole picks of the kind used to break off samples of rock and four candlesticks. The eyes and straps of two of the picks are forged from one piece of steel, the wood of the handles worked into the straps. One of the candlesticks is made so that it can be taken apart and fits into the end of the handle of one of the picks. Another has a pistol grip in place of the ordinary loop or ring, and can be closed up something after the manner of a clasp knife. A cover working with a spring fits over the socket into which the candle is inserted, and is so arranged that as soon as the candle is consumed even with the top of the socket the cover flies forward and extinguishes the candle. In addition, Mr. Bray has still another folding candlestick, made to be carried in the pocket. It is so arranged that either the hook or spike can be used, or both can be folded back and the stick carried in the hand. Another stick has a knife attachment connected with the hook for cutting fuse, an arrangement for splitting the fuse and ripping open the paper that covers giant powder in case it is found necessary to crowd it into a small hole, and also an appliance for crimping the cap. This stick is also provided with the automatic extinguisher.

The "Electro-Zinc" Process, and Experimental Researches Which Led to Its Development.

NUMBER II—CONCLUDED.

By W. BETTEL, Johannesburg, S. A.

Although the commercial use of sodium amalgam dissolved in excess of mercury for gold precipitation seemed out of the question, as it took 40 ozs. sodium to precipitate 1 oz. of gold, yet I availed myself of the reaction to rapidly assay cyanide solutions by shaking up in a stoppered cylindrical separating funnel from 200 to 1000 c. c. of the liquor to be tested with from 5 to 20 c. c. sodium amalgam, free from gold, containing 0.1% of metallic sodium for 20 minutes. The mercury separated from the solution was then dissolved in nitric acid until a final globule was obtained which was then cautiously parted in nitric acid, the residual gold washed, dried, and ignited in a porcelain crucible and then weighed. From a number of experiments made by dissolving weighed quantities of gold leaf (of known fineness) in cyanide solution, I was enabled to check the evaporation and fusion method of assaying solutions, and, finding this process reliable, I checked the sodium amalgam wet assay method. I found that, approximately, 98% to 95% of the gold was precipitated from solutions of an ounce down to 5 dwts.; 95% to 90% from solutions of 5 dwts. to 1 dwt., and, approximately, 90% to 80%, from solutions of a value of 1 dwt. down to 0.1 dwt. fine gold per ton, the latter solution being assayed by shaking 2½ litres with two consecutive lots of 10 c. c. sodium amalgam in a stoppered "Winchester quart." A suitable correction was made on weighing the gold. I found the method very useful, and the corrected results accurate enough for ordinary purposes, being within 2% plus or minus of the truth. In fact the process compares very favorably with the usual method of evaporation and cupellation and is extremely rapid.

Being convinced that electricity produced by the contact of dissimilar metal in cyanide solutions effected precipitation of gold and silver in the extractor boxes, I made many experiments on electrical precipitation, using both "local action," and electrical currents derived from extraneous sources. The first experiment made in '92 was with coarsely powdered zinc amalgam. The action was very good, only 1.5 grains gold per ton being left in a solution originally containing 1 oz. gold per ton, but the rapid decomposition of water with accompanying oxidation of the zinc speedily rendered the amalgam useless, when treating weak solutions. The next experiments were made with zinc shavings made into galvanic couples as directed by the discoverers (Dr. Gladstone and the late Mr. Tribe) with copper, lead, bismuth, mercury and silver, by dipping the shavings into soluble salts of these metals dissolved in water. Being anxious to try the precipitation process by "local action" on solutions from slimes treatment, I erected, at my own expense, a small experimental plant to prove my work on a 100 ton scale, at the New Primrose G. M. Co.'s works, in Sept., '94. In this plant I had the following novel arrangements:

1. Flocculation of slimes and collection of so-called "float" gold, by addition of lime water to the slimes pulp.

2. Continuous settlement of pulp in a dam with sloping sides and pointed base (a rough spitzkasten) with equalizing launder and baffle boards, for inflow, and discharging launder for overflow.

3. Pumping up settled slime with centrifugal pump aided by air agitation into a launder, into which was also pumped weak cyanide solution (waste liquors from cyanide works). This is the so-called "trough lixiviation." The pulp ran into tanks for settlement.

4. Air agitation in settling tanks.

5. Decantation of clear solution by decanting pipes (so-called floating syphons).

6. Precipitation of gold from solution by means of local electrical action embodying experiments with zinc-lead, zinc-copper, zinc-mercury, zinc-silver, zinc-carbon and charcoal.

When the solutions were clear and the couples clean the precipitation was excellent, a well-authenticated case giving only 0 25 grain of gold after precipitation. Charcoal also gave good precipitation

so long as hydrogen remained occluded in the pores of the charcoal, giving a hydrogen-carbon couple. The combined effect of oxidation of the zinc (in experiments with zinc-couples) precipitation of lime as carbonate, of zinc as hydrate, carbonate, and complex ferro-cyanides, and of slimes in suspension, caused the precipitation to slacken and then stop sooner or later. The oxidation effect induced me to make experiments with zinc-shavings in metallic contact with the negative pole of a small battery giving 6 volts pressure against a suitable resistance, the positive pole being connected to an arc-light carbon placed inside a porous pot filled with weak salt solution. So long as the battery was active the zinc-shavings kept clean and effectually precipitated the gold from solution. This was the experiment which led me to devise the "electro-zinc" precipitation process.

Before describing this process let me say that the New Primrose G. M. Co. paid me about £35 for the gold I won by means of "local action" (principally from "zinc-lead" couples) from solutions obtained in treatment of 99 tons of slimes, assaying 2.67 dwts. fine gold per ton.

I can, therefore, fairly lay claim to have been the first to precipitate gold (and silver) from weak solutions of cyanide produced in slimes treatment by local galvanic action, although this honor has been claimed for other and later experimenters.

The galvanic couple methods for precipitation of gold having inherent disadvantages, I set to work to remove them by taking as a starting point the experiment I made with zinc-shavings and gas-carbon as the cathode and anode respectively of an electrolytic cell.

I had before me several difficulties: First, the selection of a suitable anode; second, construction of and material for a porous cell; third, construction of the box for commercial work.

The Anode.—The employment of gas carbon or arc light carbons as anodes, either plain or coated with spongy platinum, failed on account of their disintegration and the formation of oxidation products.

Peroxide of lead plates, as used in accumulators, were out of the question on the score of expense, and the difficulty of handling large plates. Lead, in an alkaline solution, was found to be oxidized to a non-adherent protoxide of lead which left the plate open to continuous attacks by the nascent oxygen produced during the electrolysis of the solution. After numerous experiments which I need not detail I hit upon the idea of employing an insulating varnish which was thoroughly oxidized, and on which the weak current of electricity I proposed to use had little action, and making that a vehicle for holding plumbago in such a way that it acted as a conductor of the positive electricity from the lead to the solution.

This arrangement, I found, answered perfectly if a current not stronger than 0.4 ampere per square foot of anode surface was employed. A stronger current oxidized the varnish, exposing the lead plate to oxidation to peroxide with eventual disintegration.

The best varnish I find to be linseed oil (which has been boiled with litharge to form linoleate of lead) mixed with twice its bulk of brunswick black varnish (a solution of asphaltum, etc., in turpentine); turpentine is added to thin the mixture, and an amount of plumbago equal to one-third the bulk of the whole. This, placed in a shallow vessel, is painted onto the lead sheets with an ordinary paint brush, the mixture being continuously stirred to keep the plumbago in suspension. The varnish is then allowed to dry and a second coating is subsequently given.

The varnish when dry is flexible and is not readily removed except by scraping or scratching.

Porous Cells.—Being convinced by my experiments that the evolved oxygen from the anode should not be allowed to mix with the cyanide solution and so come in contact with the cathode (zinc shavings), it was necessary to devise a porous cell of sufficient strength to withstand the rough usage it would undoubtedly get from Kafirs, and at the same time be efficient. Earthenware and biscuit-porcelain plates were thought of and discarded as being too expensive; asbestos cloth was found to be too porous; animal membranes were not reliable; and parchmentized paper cotton waterproofed with di-nitrocellulose in acetone (collodion) and sundry other materials proved too weak to stand rough usage, and were too expensive.

I ultimately tried and adopted "14 oz." "cotton duck" made waterproof with either, 1, tannate of albumin; 2, tannate of gelatine; 3, chromate of albumin; 4, chromate of gelatine; 3 and 4 being rendered insoluble by exposure to sunlight.

Any of these substances as "pore-fillers" acted so perfectly that a box divided longitudinally into parallel watertight compartments with the prepared canvas would hold, in alternate compartments, weak acid and alkaline solutions without any appreciable diffusion, a solution containing 0.03% calcium hydrate passing through the box side by side with dilute sulphuric acid (.03%) in adjoining compartments, did not lose strength appreciably during the time taken to flow through the box (two hours). Electrolysis, however, was found to be quite practicable, the resistance to the passage of the current being very small.

The Alkaline Solution.—As the action of electricity on cyanide solutions at the positive pole is one of decomposition, and as, under the influence of the current an alkaline salt splits up into an acid which remains in the anode compartment (or escapes as gas such as CO_2) and alkali which (electrolytically) diffuses into the cathode cell, I used a mixture of carbonate or bicarbonate of soda with any other alkaline salt in sufficient quantity to render the solution passing through the anode compartments as good a conductor of electricity as the gold liquor to be precipitated. About .02% solid matter in solution proved to be a workable strength.

The cathode (zinc shavings) calls for no description, but the metallic cage of perforated zinc, holding the shavings and making connection, must now be described. The cages are rectangular, divided down the center by a sheet of perforated zinc soldered to the top, bottom, and ends (also of perforated zinc). There are four trays, making, with the bottom, six compartments, the edges of which are stiffened with angle zinc. The sides are formed of coarse sacking bound round the edges, fastened at the bottom by cord to the cages and at the top to each other by bands fastened by carriage hooks and eyes. The cages are electrically connected to the negative pole of the dynamo so as to collect the electricity from the zinc shavings as evenly as possible. The box consists of ninety compartments, fifty of which are narrow and canvas-framed for anodes, and forty (wide) for holding cathode cages containing zinc shavings. At the head of the box, the "alkaline" solution flows into the five smaller subdivisions or tubes in the transverse partitions, the gold solution flowing into the four larger tubes. The solutions flow up and down, precisely as if there were nine boxes, in a row, five of which were only 4 inches wide and four 1 foot 1 inch in width. In consequence, the box is rather expensive to construct, but in another installation I propose to simplify the apparatus so that without detriment to the precipitation the original cost of the box will be materially reduced.

Electrical Connections.—The box is wired in parallel (as series wiring does not seem to answer), the anode connections being soldered to strips of copper attached to the positive conductor and the cathode wires clamped between tinned copper strips 2½x1½x 1¼ inches, with screws and hexagonal nuts. The clamps are securely fastened by soldering to copper tapes connected to the return (negative) conductor. These connections have given complete satisfaction, the electricity being evenly distributed.

Current.—The current used has varied from 150 to 300 amperes at 5 to 8 volts, with an average of 200 amperes and 6 volts. In future installations the resistance of the box will be materially lowered so that a pressure of not more than 3 volts will be required.

I regret my inability to supply drawings for publication, as the process has not yet been patented in other countries, but I shall be pleased to show the box, which has been working at the Geldenhuis Deep, by appointment, to anyone desirous of learning further details.

The precipitation in this box has been excellent, a six weeks run showing an average of 1.28 grains per ton of solution after precipitation, and, on cleaning up, a small plus extraction was obtained.

Cleaning Up.—The zinc being kept clean (thereby differing from the zinc-lead method I first introduced) and active by the current, it may, with economy and satisfactory results, be transferred to the ordinary zinc precipitation boxes in sands plants, or, as the precipitation will be perfectly satisfactory, at the rate of 100 tons of solution per day passing through a small box (of 9.6 tons cubical capacity) for fully six months, the precipitation may be allowed to proceed for any convenient length of time (say 3 months) and the precipitated gold recovered by a sulphuric acid cleanup, properly conducted, followed by fluxing with a calculated quantity of an oxidizing agent and other fluxes, producing a slag which is slightly alkaline. The slag so produced yields 90% of its (small) gold contents by amalgamation in a barrel, the material being previously crushed to pass a 900 mesh screen.

Costs. — Under the above conditions (a three-monthly cleanup) the costs based upon figures obtained in actual practice will be approximately 1.93d per ton of solution treated. To this must be added interest on plant which, at 20%, will amount to .78d per ton, of solution and royalty 1.8d per ton, or a total of 4½d per ton of solution. Taking two tons of solution precipitated per ton of slimes treated, this will equal 9d per ton of slimes.

This cost will be considerably reduced by using boxes of larger size, one of which would be sufficient for a slimes plant attached to a 100-stamp mill.

I estimate, as the result of my trials, that this process will give at least 6d (per ton of slimes treated) more profit than any other process at present existent.

THE Manhattan Elevated (N. Y.) road is to change its motive power from steam to electricity, a work of enormous magnitude.

Notes on Experimental Metallurgy.*

NUMBER II.—CONCLUDED.

By J. E. CLENNELL, Salt Lake City, Utah.

Where the panning test shows clean coarse gold, amalgamation naturally suggests itself. Various more or less ingenious devices have been proposed for imitating, on a laboratory scale, the action of the stamp battery with amalgamated plates, or of the process of pan amalgamation. I do not know of any, however, which is generally satisfactory—they are all either too bad or too good. The proposals made from time to time by so-called practical assayers, and which are occasionally published by the mining papers, are sometimes almost ludicrous. One man grinds his ore in a mortar for several hours (often with addition of cyanide), pans out the residue, and collects his floured mercury by doctoring the concentrates with nitric acid. He then proceeds to "retort" his amalgam by heating it in a procelain capsule over the flame of a spirit lamp, or in the muffle—presumably the inevitable losses in the latter part of the operation are intended to counterbalance the illegitimate gains in the nitric acid treatment. Others agitate amalgamated copper strips in bottles with ore and dilute caustic soda, trusting in Providence to prevent the amalgam being scoured off by the action of the sand. A method which seems promising, is to wash the ore, crushed to a suitable degree of fineness, over a shallow copper dish, amalgamated all over the inner surface except at the rim. The ore is added spoonful at a time, washed backwards and forwards for a few moments, so that it spends out in a thin layer, then washed off and a fresh spoonful added. The difference in the assay of the originals and residues indicates the amount extracted by amalgamation. The difficulty with this method is to keep the plate bright. It must be very carefully cleansed with caustic alkali, cyanide or salammoniac immediately before using, and unless the ore is absolutely free from base metal compounds, tarnishes rapidly during the progress of the test. I am induced to think the results of this and other methods, where an attempt is made to wash the ore over an amalgamated plate, are considerably lower than would be obtained by actual plate amalgamation on a working scale with the same ore. Comparatively few laboratories are able to include a small stamp mill or grinding as part of their outfit, but some such appliance would seem to be the only reliable means of making an amalgamation test.

For reasons above given, an investigation of the merits or demerits of the cyanide procees as applied to the ore under consideration, will almost always form an essential part of the experimental treatment, and it will be worth while to discuss in greater detail the methods of examination to be adopted.

In cyanide treatment there are so many factors capable of modification, that it is seldom, if ever possible to determine, off-hand, what is the best system, or indeed whether the ore can be treated at all.

Nevertheless we have found that a system of preliminary qualitative tests often gives a large amount of useful information. These tests are simple and can generally be executed in half an hour or so; they often go a long way towards deciding whether we have to deal with a cyaniding ore, or not. It would be beyond the scope of this paper to go into minute analytical details, with which most of you are quite familiar, but I may mention that the tests we have found most useful are made on two portions of the crushed ore, one of which is agitated with water, and the other with cyanide solution of the strength commonly used in pratice, say from .1 to .2%. These are then filtered after standing a few minutes and the two filtrates examined for various substances in solution.

The water filtrate will of course be examined for soluble salts of iron, iron, copper and other base metals, for acidity and for soluble sulphates and chlorides. These tests will show whether a preliminary waterwash is necessary or advisable.

The cyanide filtrate should be tested especially for soluble sulphides, ferrocyanides, sulphocyanides, copper, zinc, and for reducing power. I will here detail a few tests which we are in the habit of making with this liquid, and which may possibly not be familiar to all of you:

1.—On adding hydrochloric (or any other) acid a white turbidity is frequently observed. This is sometimes given as a test for alkaline sulphides, but a similar turbidity may occur when no sulphide is present, for example, with certain compounds of zinc or copper.

2.—If after adding hydrochloric acid in slight excess, disregarding the white turbidity formed, a few drops of dilute potassium ferrocyanide be added, a characteristic reddish brown tint or precipitate occurs when copper is present even in very small quantity. A white flocculent precipitate formed under these circumstances, and soluble in alkalis, often indicates zinc.

3.—A solution of lead tartrate in excess of caustic soda is a convenient reagent for detecting soluble sulphides in cyanide solution. Ordinary lead salts

---

*Journal of the Chemical and Metallurgical Society of S. A.

give a white precipitate of lead cyanide, often obscuring the sulphide reaction when the quantity of sulphide is small, but the tartrate solution gives no precipitate with pure cyanide. Very small quantities of alkaline sulphides are, however, detected by the black or brown coloration.

4.—The test for reducing power is made by acidulating some of the solution with sulphuric acid, and adding a few drops of dilute permanganate. In some cases this reaction can be applied quantitatively, but it is well to remember that this reducing action may be due to a variety of causes, and it is produced by ferrocyanide, sulphocyanides, sulphides, organic matter, etc. Where this reaction is strong, oxidation will probably be necessary, either before or during cyanide treatment.

Having, by these preliminary qualitative tests determined the general behavior of the ore towards dilute cyanide solution, we next proceed to make a series of small scale quantitative tests, in order to obtain definite information on the following points:

1.—What is the most economical degree of fineness to which the ore may be crushed for subsequent cyanide treatment?

2.—What is the best strength of soultion to use?

3.—What is the best proportion of solution to ore?

4.—What length of time is necessary for satisfactory results?

5.—Is it necessary to use alkalis?

6.—Is it necessary to give oxidation?

7.—Is it necessary to give any preparatory treatment?

In many cases these questions may be answered with tolerable accuracy by means of tests on a scale of two pounds, made in the manner which I shall presently describe. It is always best, however, to confirm the result on as large a scale as possible, as the conditions of practice may be much more closely imitated when operating on a ton of material than when only two or three pounds are handled. Some of you may ask—"Why not make the tests on a large scale at once?" This would doubtless be the best course to take if we had command of unlimited material, labor, time (and last but not least) cash. It will easily be seen however, that if we use up the whole of our available material in a single tests, and the result is not satisfactory, we have no means of trying the effect of some different system of treatment. Experience has, in fact, shown us that it generally pays to make the small scale tests first, as a large number can be made simultaneously with far less expenditure of labor and money than a single large scale which ought in all cases to follow. It must be distinctly understood, that the small scale results are not to be taken as an exact indication of the behavior of ore in practice.

The general method we have adopted in carrying out the small scale tests is as follows:

The charge, generally consisting of two pounds of the material to be tested, is placed in a wide-mouthed glass jar, capable of being fastened water-tight by means of a glass stopper provided with an india rubber ring. When the jar is closed, the stopper is held tightly in place by a wire spring fastener. After adding the required amount of solution, the jars are agitated for several hours by any convenient mechanism, such as a Kafir. Where a number of tests have to be made simultaneously, a simple and effective arrangement is as follows: A wooden disc is caused to revolve by means of a belt connected with some source of power. Holes are cut in the disc to receive the jars, in which they are secured by elastic bands passing over suitably arranged hooks. As the disc revolves, each bottle describes a complete circle, and by properly regulating the speed a thorough agitation is secured, each test being treated exactly alike. After agitating for as long as may appear necessary, the jars are allowed to stand until the contents have settled, and the clear liquid then drawn off by means of a glass siphon.

If it is desired to continue the treatment, a fresh wash is given, and the jar closed and agitated as before. If the test is to be brought to a conclusion, the contents of the jar may be transferred to a large funnel and washed with water, or they may be diluted by stirring in a bucket, with a large volume of water, allowed to settle, and the clear liquid decanted. The latter method would naturally be adopted when it is desired to ascertain the "total undissolved values" in the residue.

In all cases the residue is dried and assayed, and the result thus obtained compared with the assay of a carefully selected average sample of the original ore. Sometimes it is advisable to check this result by evaporating the whole, or a measured fraction, of the liquid siphoned or filtered off, and determining the gold and silver in the evaporated liquid.

In the first instance the ore is crushed only to such a degree that a thorough mixture can be made and a proper sample taken. A series of tests can then be arranged under any required set of conditions, *e. g.*:

1.—Ore crushed to 10, 20, 30, 40 and 60-mesh respectively, treated in each case with same strength of solution (which should be rather stronger than will probably be required in practice), the same quantity of solution, and for the same length of time.

2.—Ore crushed to the mesh found most advantageous in the previous series, treated with solutions of .01, .05, .1, .2, .5% respectively, other conditions the same in each test.

3.—Ore crushed to suitable mesh, treated with solution of strength found most advantageous in previous test. Solution added in the proportion of 1, 1¼, 1½, 2, 3, 4 tons per ton of ore, other conditions alike. In this case, where the volume of solution to be used is large relatively to the amount of ore, the liquid would naturally be added in several successive washes, settling and siphoning off between each.

4.—Ore crushed to required mesh, treated with required amount of solution of required strength. Treatment stopped after 1, 2, 3, 4, 7, 14, days contact.

The qualitative tests above described will enable us in some measure to decide whether alkalis, oxidation, or preliminary washing are required. When such a course appears advisable, a similar series of quantative tests may easily be arranged using varying quantities of lime of different oxidizing agents, etc.

These bottle tests furnish a large amount of interesting and sometimes valuable information, and occasionally reveal unsuspected peculiarities in the ore which require careful attention when it is to be treated on a larger scale. One fact which is likely to be forced on our observation, is that the strength of solution is of far less importance than the proportion of solution to ore and the time of contact. This point is clearly illustrated in what I may be permitted to call the classical series of experiments made by your member Mr. W. A. Caldecott, and detailed before the society at your meeting of November 21st, '96.

On some future occasion I may have the opportunity of describing our methods of treating ores experimentally on a larger scale, and the system of hydraulic separation adopted for slimy ores; the question of determining cyanide consumption by laboratory tests is also a subject on which I have not touched, but I fear I have already exceeded all reasonable limits, and have perhaps already laid myself open to a fusilade of criticism.

When experimenting on a larger scale, say from 300 pounds to one or more tons, we aim at imitating as closely as possible the conditions of practice, using leaching or agitation tanks which are in all essential respects models of those employed in the commercial treatment.

Some factors, as for example, the depth of overlying material in sand tanks, which may in some cases exert an important influence on the extraction from the bottom layers of the charge, cannot of course be reproduced on the experimental scale, but in the main the results of such tests are comparatively safe guides to what may be expected in practice.

If in what I have laid before you I have in any measure removed the stigma which unfortunately still attaches itself to the results of experimental metallurgy, I shall feel amply rewarded.

Latest Progress in the Application of Storage Batteries.*

NUMBER III.—CONCLUDED.

By JOSEPH APPLETON.

We will now consider the use of storage batteries in connection with isolated plants in large office buildings and stores using electric elevators.

The modern office building, with its fifteen or twenty stories, together with the demand for quick elevator service, has greatly increased the use of high-speed electric elevators. The nature of the work the elevator has to perform, and the fact that the power required to start it is from two to three times the hoisting power, cause the elevator load to be an extremely fluctuating one, no matter how carefully the operation is watched.

The Commercial Cable building in New York City is an excellent example of what can be done with the operation of an electric plant of this description. The building is wired for about 3500 16-candle power lamps, 240 volts, and has six screw type high-speed elevators. The generating plant consists of two 300 H. P. water tube boilers, two 225 H. P. engines directly connected with two 150 kilowatt generators, and the storage battery consists of 120 cells, each containing twenty-seven plates. The capacity of this battery is as follows: At 260 amperes, 1620 ampere hours; at 520 amperes, 1040 ampere hours; at 650 amperes, for the one hour rate.

Before the battery was installed it was found necessary to run one generator for the lighting circuit and one for the elevator circuit, the fluctuations of the latter causing the lamps to be unsteady if both were run from the same machine. The method of operation is as follows:

The elevator circuit is connected directly across the terminals of the battery and the battery is being constantly charged by means of a constant current booster which boosts the current from the lighting generators. By a special winding on this booster the amount of current it allows to pass from the generator to the battery and elevators is maintained practically constant.

Of course, when there is no elevator load, which occasionally happens (all the elevators standing still), the entire amount of current passed through the booster is used for charging the battery. When a heavy elevator load comes on, this boosted current is diverted from charging the battery into the elevator circuit, the battery discharging in parallel with it as may be required. In this installation the booster is passing about 250 amperes; thus when the battery was discharging at 350 amperes the total elevator load was 350 plus 250, or 600 amperes.

The centralization of generating plants, and their location in districts where the facilities for obtaining coal and water are good, has developed the system of high tension alternating transmission, and the distribution of direct current through rotary converters. This seems to be the one which will be employed in most of the large engineering undertakings to be solved during the next few years. The advantages of direct current for distribution over the alternating are so marked that, at least until further improvements are made in alternating current distribution, the direct current will undoubtedly be the one most generally used. With this system of large central power house and substations for distribution through rotary converters, storge batteries are almost essential. They reduce the size of the generating plant in the first case, and also the size of the rotary converters, and enable them both to be operated with a much greater load factor than would be possible without. The installation of the Hartford Electric Light Company was the first of this description in this country, and has proved the many advantages which were claimed for such a system.

Most of the plants dealt with so far have been those of a large size, supplying a large amount of energy. It must not be imagined that storage batteries are applicable only to these large stations, the results obtained from their use are just as satisfactory in the case of smaller stations, but I have referred to the larger ones as being of more interest. I will, however, give the results obtained in one of the smaller type.

The Claremont Electric Light plant, Claremont, N. H., is a small plant operated by both water power and steam. The plant consists of two Edison bipolar dynamos running on the three-wire system and an arc light service supplied by fifty lights and Thomsom-Houston dynamo. In connection with the Edison dynamos, which are operating on the three-wire system, there is a battery plant of 134 cells containing eleven plates in each cell, 10″ square. These batteries are operated directly in parallel with the Edison dynamos, and relieve them of a portion of the load during the time of heaviest amount. They also help out steam plant, enabling the water power to be used to its fullest advantage.

Take, for example, the following figures for the month of January, 1896; before the batteries were installed it was found necessary to run an auxiliary engine 180 hours to supplement the water wheel. During the same month in 1898, after the battery was installed, the same conditions as regards water power prevailing, the station load was 33% heavier, and it was only necessary to run the auxiliary steam engine 133 hours during the month.

The plant itself is not elaborate, but nevertheless satisfactory results are obtained, which show that the storage battery is an economical adjunct in stations of this sort.

There is one application of storage batteries in connection with central stations which I believe will in time become very general, but which at the present time has only been tried in a few instances. It is the use of storage batteries in office buildings, stores, etc., instead of the usual isolated plant or direct supply from the central station. The method of operation is as follows:

During the few hours of maximum load at the central station the storage battery supplies the entire current for the building, it being disconnected from the street mains. During the hours of light load the building is connected with the street mains and the battery charged from them. By this means the central station can take as customers these buildings, and only have them on their system during the hours of light load. This is a class of customers which is not profitable for the central station in the ordinary way, as they have a large number of lamps which are only used for short period, and that at a time when the station has its maximum load. This means that they have to provide capacity for these lamps, and yet the plant is only needed for an hour or two a day. By this method a central station can also take customers having a fluctuating power load without feeling its disturbing effect on the system, the battery maintaining an even pressure at all times. This is particularly advantageous when the fluctuating load is some distance from the power house and the feeders are not large.

*Condensed.

AT Redlands, Cal., on the 11th inst., E. L. Crawford, while standing upon an iron transformer struck his head against a live copper wire carrying 30,000 volts of electricity to Los Angeles, making a short-circuit and blowing out the fuses at the power house in Santa Ana canyon, but received no further injury than a slight burn on the scalp and a stunning fall to the ground.

Mining Summary.

ALABAMA.

Alabama mine inspectors report that for the year 1898 Alabama produced 6,504,960 tons of coal, an increase over the previous year of 611,189 tons. During the year the miners worked six days every week. There were no labor troubles nor prospects of any. Miners are considered certain to get an advance of wages with the advance in the price of iron predicted for March 1.

ALASKA.

The Treadwell store on Douglas island has outfitted several prospectors. Some interest is occasioned over the reported discovery of placer diggings four or five miles back from the shore.

The *Record* reports a strike on McDonald creek in the Atlin country. The creek is but five miles in length and is on the American side near the boundary. Claims are 250 feet square.

ARIZONA.

J. A. Fleming of Phœnix is reported to have refused $750,000 for a half interest in the Black Warrior copper mine in southern Arizona.

At Ehrenberg the placer mines of Polomas district are reported taking more money out of the gravel now than for many years; in Ehrenberg a strike has been made yielding from $10 to $15 per day.

Lindstrand & Hemple, owners of the Hard Trial mine, three miles from Crowned King, will this season run a 10-stamp mill.

A river dredging scheme is in progress to work the bed of the Colorado river above the Grand canyon, Arizona. The company formed for this purpose has laid claim to 150 miles of the river above Lee's Ferry. A dredge is in course of construction which will be operated by electricity. R. B. Stanton is in charge of the work.

Journal-Miner: M. S. Taft is shipping ore from the Sterling mine on Big Bug.——The drift on the 500-foot level of the Crowned King mine in the Bradshaw mountains has been run for 15 feet through the ore body recently discovered. The ore extends both above and below the drift.

Tempe *News*: M. McLeish has purchased a large dump of tailings at the Mammoth mine at Goldfield, forty miles east of Tempe, for cyaniding. There are 30,000 tons of tailings in the dump.

Prescott *Courier*: At the Senator workmen are engaged in lowering the floor of the tunnel preparatory to sinking the shaft below the intersection of the crosscut with the vein. When this is finished the hoisting plant is to be placed at the intersection and power for the underground workings of the mine will be directed from this point. It is expected that two months will elapse before the shaft sinking will be under way.

CALIFORNIA.

Amador.

The Peerless G. M. Co. will operate near Jackson.

The Pocahontas at Drytown shipped its first bullion last week from eight tons of sulphurets. When the west ledge is tapped on the 700-foot level ten stamps more will be added to the mill.

Supt. Voorheis of the Lincoln mine, at Sutter Creek, reports that the present company was incorporated February 12, 1898; active work commenced March 4th. A new steam hoist was erected; work of cleaning out and retimbering the old shaft began July 4th. On December 4th the shaft had been sunk and retimbered down to the water level, 465 feet from the surface. The reason the shaft was dry to this depth was that the water had run to the Mahoney mine on the south through the old drifts made in the early workings of the two properties. From the 500-foot level down the old timbering was in good condition to the 800-foot level, which point was reached Jan. 17th, '99. When the water was encountered at the 465-foot level a small steam pump was put in position and the water pumped into the large skips and hoisted to the surface. Forty-three days were consumed in unwatering the shaft to the 800-foot level, during which time 2,979,000 gallons of water and 682 skips of waste were hoisted to the surface. All of the old center braces were removed and new ones put in, as the position of the old braces made the compartments too small for the large water skips to run in. The old wooden track was also taken up and removed and heavy iron T rails put in. Three old style 8-inch Cornish pumps were taken out. The sump is being cleaned out and preparations to sink the shaft 400 feet deeper are being made. Statement of receipts and disbursements shows: Received from the stockholders, on eleven calls, $33,000; cash from 213 tons of rock crushed at the Zeila mill, $9213.66. The disbursements aggregate $40,762.10; balance cash on hand, $1451.56.

The new vertical shaft of the Wildman-Mahoney at Sutter Creek is down 400 feet, with work progressing as rapidly as possible. The new reservoir is completed and 4000 feet of water pipe is in, completing their system for water power throughout the property.

The shaft in the Amador Queen No. 2, near Jackson, which is now down about 800 feet, has been cutting some valuable stringers of ore.

Record: The Pocahontas at Drytown shipped its first bar of bullion last week.——The 10-stamp mill on the Allison mine northwest of Plymouth is to start up March 1st.——The shaft of the Bay State, now down 750 feet, will be sunk to 1000 by contract.——The dumps of the old Pacific mine at Plymouth are to be run through Huntington mills. There are many thousands of tons of this material.

Butte.

The Enos Co. fired their drifts at Cherokee last Sunday. There were three drifts 60 feet in length and 40 feet apart, under a bed of gravel 50 feet deep, with an immense pile of boulders on top, and when J. Enos rammed the plunger the whole mass of from 7000 to 10,000 tons of gravel and boulders rose several feet in the air. The Costa mine is near by and each is working fifteen men. Both mines are worked on the co-operative plan.

The Platt dredge was launched last week south of Oroville. The dredges now running there are reported taking out from $150 to $300 for each twenty-four hours for each boat.

Calaveras.

At Camanche the Eastern Co. which has been boring for gravel has, after four months work, struck the channel at a depth of 150 feet. Steam power is used in boring. The superintendent is H. McSorley.

The copper mines at Campo Seco, idle for a long time, are again in operation. On the Constellation mine, owned by C. Boerger, a new hoist has been erected, the Higby shaft has been retimbered and preparations are being made to sink several hundred feet.

Echo: L. P. Drexler has brought suit against W. S. Edwards et als. for $9673, alleged balance due on price of Mayflower mine at Murphys. It is stated that defendants bought the mine for $14,000, paid $4327, leaving $9673 due.——Thirty stamps are reported at the Thorpe mine at Fourth Crossing.——Most of the Utica Co.'s mines and mills are running.——The electric motor for operating the machinery at the Lightner mine is ready to be put in place.

Del Norte.

The black sand mine at Crescent City is being operated. The old style of boxes and copper plates is the method employed in extracting the gold. The *Record* says this method has proven superior to any of the innumerable fine gold saving machines that have been put up on the beach.

El Dorado.

A 5-stamp mill is being built on the quartz mine of F. Thomas & Co. near Gold Hill.

The German mine below El Dorado worked by P. C. Dubois for the past year or so is being developed. A 10-stamp mill has been running for some time and the company is now adding ten stamps more.

Lack of water prevents work at the Gopher-Boulder.

At the German mine below El Dorado the company is increasing the capacity of the mill to twenty stamps.

Kern.

John G. Stephens, a miner working in the Yellow Aster mines, fell from a ladder last Monday with fatal effect.

C. J. Berry, the successful Klondiker, who recently bonded Amador Co. property, is now in Bakersfield with others to lease the asphaltum beds in the vicinity of Asphalto.

At Johannesburg the Red Dog mill is running on ores from the Gold Coin, Annex, Kinyon, Sunshine and Pinmore mines. They have begun work on their 20-ton cyanide plant, to be in operation April 1st.

The Amarita mine at Randsburg is reported sold.

Randsburg *Miner*: In the Minnehaha mine a 5-foot ledge has been struck that is good for $20, and in the middle of this ledge is a 6-inch vein worth $200 per ton.——The Warrington mine at Havilah has been sold to the Warrington M. Co. by G. C. Kirby. As there are $30 worth of revenue stamps on the document, it is probable that the price paid was $30,000.

Los Angeles.

Mining Review: Dr. G. P. Gehring of Los Angeles has purchased the old Escondido mines near Acton.

Madera.

At the Gambetta mine at Grub Gulch the new shaft is to be 1000 feet deep.

The Flying Dutchman mine at Coarse Gold has been bonded; the main shaft, now 200 feet deep, is being sunk deeper.

Mono.

The Par Value M. & M. Co. has incorporated at Bridgeport; capital stock, $50,000—$6500 paid up. The mine is eight miles from Bridgeport. This spring the owners will build a mill.

Nevada.

Judge W. B. Wallace of Visalia has bought the interest of D. R. Bullard in the Gravel Hill hydraulic mine.

Locklin's mill, in Willow valley, is crushing twenty-five tons of ore from La Belle claim, on Deer creek. J. L. Postlewaite has charge.

Hecker & Coughlan are reopening the Locklin ledge in Willow valley and are hauling a crushing of twenty-five tons to the Locklin mill. They are working through a tunnel over 300 feet long. The ledge is from 12 to 15 inches thick. Ore taken from this claim thirty years years ago paid from $75 to $80 per ton.

The Champion M. Co. has forty of its seventy stamps going.

Herald: The California mine, on Gaston Ridge, contains two great quartz ledges from 5 to 9 feet thick, and the ore runs from $6 per ton up to fancy figures.——J. G. Cohoe has taken a bond on the Grey Eagle, at Maybert. He intends putting in a machine and driving the tunnel 500 feet farther.

Placer.

Operations in the Azalea mine were resumed last week.

W. McDaniels is taking out some rich gravel at the McDaniels mine near Rich Flat. One pan of gravel is said to have been worth $53.

There is being hauled to the Crandall mine, North ravine, 2000 feet of 10-inch sheet iron pipe.

Work has been resumed at the Blue Canyon Co.'s mine.

The Bear River Hydraulic Co.'s mine near Colfax has just commenced operations on a small scale.

The Big Dipper mill is being repaired.

Riverside.

(Special Correspondence).—The population at Virginia Dale now numbers 150. This camp is on the Colorado desert fifty miles northeast of Walters station on the Southern Pacific railway and about thirty-five miles south of Cadiz on the Atlantic and Pacific. The mills are on a dry lake north of the Monte Negras hills at an altitude of about 1500 feet. There are four stamp mills—three of two stamps each and one of one stamp. Water is obtained by sinking in the Dry lake to a depth of about 100 feet. The group of hills lying southerly from Virginia Dale rise 1500 feet above the valleys, are absolutely destitute of verdure of any kind and are blackened by the burning rays of the sun. The formations in which the veins occur are diorites of many textures and colors from rather coarse gray to dense black varieties. The larger masses are light colored and are traversed by the smaller green and black dykes and it is with these latter that most of the veins are associated. Some occur at contact of the dykes and massive rocks and others are wholly within the dykes themselves. The veins are fissures of probably great depth and continuity. Many of them outcrop boldly for hundreds of feet. The croppings usually contain large amounts of iron oxides, limonite and hematite, but in depth sulphides of iron, copper and zinc appear. The fissures range from a few inches to 6 feet in width and the ore is high grade, running from $10 to several hundred dollars per ton. Gasoline engines are used for power. This is one desert camp where success is being made, and there are still good opportunities. On the south side of the range, about seven miles from Virginia Dale, are a number of very promising prospects which require some capital for their further development.

Virginia Dale, Feb. 20th, '99.

Shasta.

At the Mount Shasta Gold Mines, Ltd., they are down over 200 feet, stoping and developing in the several drifts. Forty men are employed; the number will soon be increased to sixty. The hoist is run by a gasoline engine. They are turning out from ten to fifteen tons daily, and as soon as the output is increased a more extensive hoisting plant will be installed. W. G. Scott is Supt.

What appears to be a quicksilver prospect has been located on Gold Hill, east of Millville.

The Golinsky copper property near Kennet is being developed under a bond by W. Kemp for the Lewisohn Bros., New York City.

The Bayha copper property at the head of Stillwater is to pass into the hands of German parties.

Sierra.

It is again locally rumored that the Alaska mine, so long idle, is to start up under a new management, the mine to be drained by a siphon.

About fifty men are now employed at the Mountain mine at Sierra City.

At Pike City, because of the scarcity of water there is little mining going on. The recent storms only soaked the dry ground and did not increase the springs to any extent. F. M. Thomasson contemplates putting up a mill.

Enterprise: The Oriental mine, at Alleghany City, closed down last week to wait for spring.

Siskiyou.

The Cape mine on the north fork of Greenhorn has started up. G. E. Ward is the new superintendent.

E. Wallace has bonded most of the Yreka creek property and expects to put in a dredge.

H. Harris, Humbug, has struck a 3-foot ledge on the Mocking Bird claim.

Journal: E. T. Wallace has bonded ground along Yreka creek to a new company, who intend putting in a dredge to work it next summer.——G. Simmons will work the Quinne & Simmons mine at Hawkinsville. Water is pumped from Shasta river to the top of the hill, over 400 feet, and emptied into a ditch running towards Hawkinsville to supply giants used in sluicing down the banks.——The Jillson & Roberts quartz mine at Henley has been paying handsomely.——Rich quartz mining property has been discovered by G. Carr and others near the head of Union creek in the Coffee Creek mining district, on both sides of the Trinity and Siskiyou county boundary line at the headwaters of the Salmon river tributaries above Cecilville, where considerable mining will be carried on during the coming summer.——The new quartz mill near the Cherry Hill mine on Cherry creek has started up.——Dredging of Yreka creek from the boundary of Yreka to Shasta river will be an extensive enterprise, as the introduction of a steam dredge will cost about $40,000. It will scoop up the gravel down to bedrock, and there will be an abundance of water at bedrock to furnish a good head for sluicing. The dredge system is now being worked on the beds of various streams throughout the State with good success, and will no doubt prove profitable in Yreka creek.—The Minetta B mine, on Klamath river, in Happy Camp district, is being energetically worked. The giants are supplied by a ditch running 2500 inches of water, carried across the Klamath in a large pipe on a bridge held up some 10 feet above the stream by 3-inch wires. In place of the building of long ditches from streams as heretofore, for conducting water to irrigate and mine, the new system of electric pumping power is much cheaper and more advantageous. With a fall of a few feet by damming or building a short ditch at a stream sufficient power can be gained to operate an electric dynamo, by which pumps can be worked for raising the water into flumes or ditches close to where needed, thereby saving loss by evaporation and seepage in building long ditches around mountains and on high lands for grade, with more crooks and turns than the most crooked rivers.——D. B. Provost is at Jenny creek superintending the putting in an assay plant and the construction of buildings necessary for the prosecution of prospect work on the quartz claims.

News: The old Wright & Eastlick mine, at Oro Fino, started one giant last week. They shut down on the 3rd inst. on account of the freeze-up.——The Campbell placer mine, near Oro Fino, has started up.——The Beaver Creek mine, near Helena, will be operated extensively the coming summer. C. L. Knapp is Supt.——At the Albert Winder power claim near Orofino Bar nuggets of pot metal are occasionally found.——The Siwash Co. expect to crush 500 tons of ore.——The Schell & Gardner hydraulic mine at Oro Fino will start up as soon as they get sufficient water.——At the Spencer mine, on Humbug, the crosscut tunnel is being run as fast as a double shift can do the work. It is now in over 500 feet, and it is expected to cut the ledge at 700, which will give them a depth of about 400 feet.——The Gray Eagle M. Co have thirty men employed at their Quartz Valley mine. They are sinking on the ledge from the crosscut tunnel and are now down 80 feet. A tunnel is being run on the ledge from the 50 foot level of this shaft. Stoping is going on.——The Good Ball mine is working a furnished force with good results.——At the Black Bear mine they have opened up some rich rock in the southern part of the mine.——Hickey Bros. are developing the White Swan mine.——H. Foxley is running the Lanky B. o. on Eddy's Gulch.

Journal: The San Francisco Co., working the old Eastlick and Wright mines at Oro Fino, are now running their giants under a full head of water in the ditches fed from the snow-covered Salmon range, and the creeks leading therefrom, and will have a good supply for several months.——The new quartz mill at Cherry Creek is running on ore from the Cherry Hill mine of Hunter & Co.——The new company bonding the Yreka Creek ground from Yreka northward to Shasta river, will soon prepare to set up the dredge.

Stanislaus.

Oakdale *Leader*: The Alta mine, near Knight's Ferry, operated several years by T. M. Lane, has been closed down, but will soon be reopened on an extended plan for further developments. A 60-stamp mill is to be built.

Trinity.

The Van Ness placer mine at the Feeney place, Trinity river, created a sensation there, a leaser having taken out a chunk of gold weighing a pound and another weighing sixteen ounces and $30 worth of fine gold, all in one wheelbarrow full of gravel.

At New River miners are not idle because of lack of water; but as is usually the case, many did not have flumes and bedrock ditches in working condition when the water came. In other instances snow is an obstruction to work, but the outlook for a good mining season is better than it has been for years. Little work is being done in the Ridgeway and other quartz mines on New River.

Tuolumne.

The App mine near Quartz has closed down. Lack of water is given as the cause.

The Golden Gate mine at Sonora also shut down this week on account of lack of water.

The Santa Ysabel mill cleaned up $11,000 net gold in twenty-two days in January. Gen. Mgr. Buckminster will investigate the question of adding twenty stamps to the mill.

Union-Democrat: The Dreisam shaft near Arrastraville is down 230 feet and sinking is in progress. A drift is being run at 200 feet both ways from the shaft, now in 150 feet each.——Sinking is in progress at the Confidence mine at Confidence.——At the Buchannan the new shaft is being sunk to reach the vein 200 feet under the deepest old workings.——The Hope mine, a claim on the Bonanza vein, has 100 tons of ore out which will be crushed in Mason's mill.——The Black Oak, Soulsbyville, has completed a 10-stamp addition to its mill and will add an additional ten stamps, making a total of forty stamps. The duty of the stamps is about one and one-half tons per twenty-four hours, a 60-mesh screen being used.——Machinery for the Lost Fox mine on the east lode near the Buchanan mine is being shipped in.——Grading on the Sierra Railway is now in progress east of Sonora, and the extension in the direction of Summersville will be built this season.

Jamestown *Mountaineer*: F. M. Miner, who has been superintendent of the Valparaiso mine at Tuttletown for the past three months, has left for Chicago, the company he represents having thrown up their bond on the mine.——At the Excelsior mine above Confidence three shifts are being worked.——Work on the new 20-stamp mill for the Bown M. Co. at Tuttletown progresses.——The 1800-foot tunnel on the Old Tuolumne mine at Wet Gulch is being retimbered throughout.——The additional ten stamps being put in at the Black Oak mill, Soulsbyville, are ready to begin. A canvas plant is being erected.——The Philadelphia gravel mine, operated by the Stockton Gravel M. Co., is ready to start up.——At the Deadhorse mine, Carters, operations were resumed last week.

COLORADO.

BOULDER COUNTY.

The Modoc shaft at Ward is to be sunk 200 feet farther. It is now 340 feet.

A strike of gold ore is reported in the Mamie Watson claim in Camp Dewey.

From the Golden Age mine, Jamestown district, a recent shipment of seventeen tons yielded $17.30 net. The high-grade ore ran 696 ounces in gold and 560 ounces in silver to the ton, the second class 1½ ounces gold and 22 ounces silver.

CHAFFEE COUNTY.

The Sedalia mine near Salida is reported producing twenty tons of ore a day, which at the present price of copper nets about $450. Twenty-seven men are employed at the mine; the payroll amounts to $2000 a month.

The Queen and Queen of Hearts mines, copper properties, are being developed. They have recently cut two veins in the Queen 20 to 25 inches in width. Tests give a good per cent in copper and $17 in gold.

CLEAR CREEK COUNTY.

In the Anchor mine near Freeland in Fall

River district has been found ore running $375 to the ton.

EL PASO COUNTY.

At Victor the National Gold Extraction Co. is incorporated by Messrs. Tutt, Penrose and McNeill. At the same time, says the Victor *Record*, the purchase of the Kelton sampler at Goldfield and the Kelton reduction works at Florence was consummated by the same parties. It is the intention of the new company to increase the capacity of sampler and mill to sixty tons per day. The operation of these plants will not conflict with the Cripple Creek sampler and Colorado-Philadelphia reduction works at Colorado City, owned by the same people, the former institutions are on the narrow-guage road and the latter on the broad-guage.

The Kelton mill and sampler were completed one year ago at a cost of $107,000 and operated only three months.

The Vindicator at Cripple Creek is shipping 50 to 100 tons of ore daily.

Zeigler & Wilson on the J. I. C. on Battle mountain, Cripple Creek, have struck at 80 feet in a crosscut run from an old abandoned shaft a 2-foot vein of quartz which assays $18 to $160.

In the Favorite at Cripple Creek at the 400-foot level a sylvanite streak which has been followed in an upraise 50 feet from the shaft has widened to 18 inches, carrying values of three ounces to the ton. A find has also been made in the third level on the McPherson lease, where 12 inches assays as high as $72.

A. J. Austie has made an important find on the Pointer, south of Cripple Creek, on Gold hill. A few feet of work opened up 3½ feet of ore which will average $50 in carload lots.

Returns from a car of ore recently shipped from the Gold Dollar on Beacon hill, Cripple Creek, show a value of fifteen ounces per ton.

The annual report of the directors of the Victor G. M. Co. has been forwarded to the holders of stock. During the past two years it has ranged as high as $7.50 per share in Paris, on the dividends of '96—$20,000 per month—and as low as $2.50 per share in Boston in '98, while the company was paying quarterly dividends of $100,000. The capital stock of the company is $1,000,000 in $5 shares.

GILPIN COUNTY.

During the past month the Concrete mine shipped 170 cords of ore, aggregating 1450 tons, all of which was treated at the Pennsylvania and Iron City mills at Black Hawk.

The Kansas-Burroughs Con. M. Co. reports an output of 313 cords, or about 2900 tons, all of which was handled over the tramway lines.

The Cook mine shipped 3200 tons of mill ore and this, with 750 tons of concentrates and smelting ore, brought the total production up to 3950 tons, being an average daily production of over 500 tons, and bringing this mine up to the first place as a producer in this county.

The property of the Sleepy Hollow M. Co., situated near Black Hawk, was sold to A. B. Seaman of Denver last week for $15,180.49, the property being sold to obtain a recent judgment against the company.

Men at work on the Clay mine are taking out ore running $10 per ton in gold. This is one of the oldest mines in the county and is credited with a production of more than $250,000, but has been idle for nearly twenty years.

The Rocky Mountain concentrator during January treated 1723 tons of crude ore, from which were shipped 428 tons of concentrates.

GUNNISON COUNTY.

(Special Correspondence).—The gold belt covers a country 12x40 miles, northeast and southwest, characterized by many different formations. Near the west end of the now known belt, for several miles west of Cebolla creek, which flows northward into Gunnison river, at a point about four miles from its mouth, the mineral zone seems to set in, and for over twenty miles up the creek good property is being found. The formation consists principally of eruptive rock altered to schist, standing on edge, but there are several places in the belt where granite covers a number of square miles. Both these country rocks are seamed with dykes. Nearly all of the larger veins or dykes are found where much volcanic disturbance has occurred.

On the Gunnison mine a shaft is down 150 feet on a large vein. Walls on either side of the vein are soft and schistose. The quartz is hard and generally of a dark tinge, in some places white. On the surface there were found copper carbonate and oxidized iron, and the ore ran $2 to $8 across a 20-foot vein. At the 150-foot station, I am informed by Mr. Holmes, the Mgr., that by 500-pound sample, taken from across the vein, it shows values of $13 on the plates and about $10 in concentrates. The copper seems to have about all disappeared; the values are all in gold, and some experiments in cyaniding will be made. Mgr. Holmes has determined to sink several hundred feet farther before building a mill.

The Midland seems to have had a series of unfortunate managers and has done but little, though it makes a good showing with a vein about 18 feet wide and ore that should mill not less than $10 and a rich streak which will run from $30 to $100 per ton.

The Vulcan mine and Mammoth Chimney are on one of these large veins. These properties have been consolidated and are worked from the Vulcan shaft. The workings are now down over 400 feet. The walls are light gray schist. At the surface were large masses of chalcedonic quartz, jasper, massive quartz and soft material with porphyry. On the lower levels it seems to be getting better with every foot of sinking. On the south wall there is a vein of solid iron pyrites 20 feet wide. At the place I measured the crosscut it runs about $2.50 in gold. Next to this there is 3 or 4 feet of native sulphur, nearly pure, which is marketed at a good profit. Adjoining the sulphur streak is found a soft zone through which rich streaks of ore occur. This ground is so soft as to require very little blasting. With no free gold, much of the sacked ore will run as high as $800 in gold. It carries about 300 ounces silver also. This mine works about forty men, has passed the experimental stage and is now a steady producer. There are no signs of copper in the ore. A vein not over 500 feet to the south will run nearly 10% copper.

Near the head of the Cebolla is the O'Brien property, with free-milling ore in large quantity. Not far below, on the same creek, I examined the Rudolph property, which is a good prospect, with about 200 feet of work. It shows about 4 feet of ore that runs $20 to $40 in gold, 4 to 5% copper and ten ounces silver. It is a good concentrating ore and has good water power.

A little farther down is the old Lot mine and mill which, I am told, are to be started up again in the spring, after having been idle for a number of years.

A new 10-stamp mill has been built two miles farther down the creek to work a large vein near the Carpenter group. Plate amalgamation will be tried.

At the Carpenter group they have a 10-stamp mill, but no development work done, hence the mill is idle.

Several miles farther to the west is the Duboise camp, where considerable work is being done. The Duboise tunnel, under the management of G. W. Griffey, has been driven 700 feet to tap several large veins which it has not yet reached. I am informed that a 20-foot vein has been cut in a tunnel on the opposite side of the creek that will run $6 per ton.

At Spencer a good deal of work has been done, but no shipping veins have been opened. There is a good 10-stamp mill at this place.

About two miles east and a little south is the Iron Cap mine, with 135-foot shaft and three levels. There are about 3 feet of $18 ore and 20 feet of $6 ore. The mine has a good hoist and 5-stamp mill. The ore carries some copper. It will make a good concentrating mine. Idle for the winter.

The Woodland M. Co. of Denver expect to develop a group of five claims near the Iron Cap when the snow is gone. Their claims look well for prospects.

About five miles farther east is the Gold Basin camp, and four miles south is the Midland, referred to before. The Tuller & Riley property gives great promise of becoming a producer of high-grade ore. Veins are from 2 to 3 feet wide and the ore will run from $20 to $500 per ton. They have opened the vein for a distance of 2000 feet, and there is good ore on the vein the entire distance. This property is just above the Gold Basin.

The Grafiin property, north of Chace and a little east, is working air drills, and their tunnel, which is in over 500 feet, has cut one of their veins 14 feet wide and runs $10 where the cut is made. They expect to cut another within 100 feet and a third about 300 feet from present breast of tunnel.

Some work is being done on large dykes on the Cochetopa creek, about five miles farther east. I will only mention one of these large dykes, which is covered by the claims known as the Red Line group. The vein is about 150 feet wide and composed of a schistose rock, with quartz, jasper, etc., all through the vein. The whole mass is impregnated with hematite iron and from a good many tests in the surface cuts shows values that make it average $4 per ton or better. There is water power enough right at the property to crush 500 to 1000 tons of ore per day. This ore has no copper at present.

There are many such dykes in the belt, and I am inclined to think they will all make good low-grade properties if worked in a large way. The ore generally must be treated on the ground, hence it is not a very good poor man's camp.

G. W. BARTHOLOMEW.

Gunnison, Colo., Feb. 16th, '99.

HINSDALE COUNTY.

Record: The Hidden Treasure mill is turning out three cars of lead concentrates per day. The mine furnishing the ore is one of the largest lead fissures in Colorado, being a continuation of the famous Ute ore shoot. The ore bodies are from 4 to 16 feet in thickness. ——The Lellly mine is working twenty-five men and turning out eighty tons of copper ore per month.——The Vermont group, consisting of five patented claims, is purchased by A. E. Reynolds.

LAKE COUNTY.

Coal is again being delivered at Leadville, the greatest trouble being in getting timbers and the mines are unable to open up any more new ground. Last week there were 1500 idle miners forced to lose time on account of the snow blockade. The Rio Grande road enjoys the exclusive business of the Arkansas Valley Smelting Co. which amounts to $60,000 per month and they have everything in fine shape at the yards of that big institution.

Many miners, charcoal burners and loggers from surrounding camps and gulches, says the *Herald*, have come into Leadville to replenish their comissary. They seem to dread snow slides and prefer to remain until this danger is past. The storm has cost mine employes large sums in the loss of wages.

A Leadville teamster last month loaded and hauled 36,575 pounds of lead sulphides in one load from the Mahala mine to the railroad station—one of the largest loads of ore on record in that section.

The Yak tunnel is in 7000 feet, being nearly 900 feet below the surface at the face.

The pumps of the Bohn shaft at Leadville are raising 3800 gallons of water per minute.

OURAY COUNTY.

At the Revenue mill at Ouray a 100 H. P. engine is put in. The Revenue now employs about 600 men.

PITKIN COUNTY.

The Smuggler mine at Aspen is reported to be making a profit of $10,000 per month by concentrating low-grade ores. Successful concentration promises to give Aspen a new lease of life.

SAN MIGUEL COUNTY.

The Euclid Avenue G. M. & M. Co. has its new 10-stamp mill and wire rope tramway, in Bear creek, in operation, daily treating from eighteen to twenty-four tons of quartz every twenty-four hours. The tramway is 2700 feet long, comprising but a single span, said to be the longest of the kind in the world. The Euclid Avenue Co. is a subsidiary company of the Colorado Exploration Co.

The Smuggler-Union mine has a vast amount of ground opened up for stoping. The ore shoot is over 5000 feet in length.

In the Saw Pit mines near Telluride some new chimneys of fine ore have been opened up and are yielding regular shipments.

In the crosscut being run for the Silver King vein in Alta basin a big strike has been made.

Ore from the new copper mines in the western part of the county has recently been found assaying over 200 ounces silver and 70% copper.

SUMMIT COUNTY.

Snow was 12 feet deep on the level at Kokomo and Robinson. Last week there was nothing but flour, potatoes and some canned goods in Kokomo to eat, and only a few days' supply of these. The fuel supply was almost exhausted. By this time the blockade has been raised.

IDAHO.

The gold output of the Pierce City district for 1898 is estimated by the mining men of that district at $75,000. This amount shows a decrease of about $25,000 from the output of 1897, which was fixed at about $100,000. This decrease is attributed to the increased activity in the line of developing quartz propositions, which has had a tendency to detract from placer enterprises, the main source of the gold output.

C. W. Stickney says of the Big Lost river mines: "The silver mines at the head of the river have entirely ceased operations for the present and the assignee of the Phi Kappa M. Co. has sold its machinery and contemplates pulling down the mill. These mines, however would pay largely if they were worked by electric drills run by water power. The late manager says $15,000 would place them on a paying basis of $60 per day, there being about 14,000 tons of silver-lead ore in sight, requiring only cheap mining and concentration to get its value out with a good margin. The White Knob M. Co. is operating farther down the river, near Houston, on what is called the Big Copper. They have sunk about 500 feet and contemplate going down until they reach water level, where they expect to find sulphide ores of a constant value and in quantity. The owners of the copper mines over on the east fork of Big Lost river are still running drifts and tunnels and developing a larger body of ore each year. This property is destined to be at some time a grand one, as the grade of ore is above the average of the American copper properties. Although no depth has yet been attained, the surface indications and ore bodies uncovered are immense, and enough ore is now in sight to start a small smelter."

E. Juessen, Mgr. American Hill mine at Elk City, has spent some time at South Milwaukee regarding the construction of a gold saver. The plant will be lighted by electricity and is guaranteed to handle 2000 yards of gravel every twenty-four hours. The buckets discharge the material into a hopper, through which it passes into a revolving screen of sufficient internal size to enable it to pass stones brought up in the bucket 18 inches to 2 feet in diameter and of sufficient length to screen and wash all the material. A series of streams of water are introduced into the interior of screen, washing the gravel as it is tumbled over and over. The size of the opening in the screen depends upon the character of the material and the coarse tailings are discharged overboard. The stone chute is built high enough and with sufficient inclination to discharge the material clear of the side of the boat. From the under side of the screen there is a discharge of all the fine material, including the gold, together with a considerable quantity of water. This is sluiced over the stern of the dredge. The buckets are of steel and have a capacity of 5 cubic feet; the dredging can be done at a depth of 45 feet. Water is supplied to the sluices by a centrifugal pump.

In the Crackerjack mine, Buffalo Hump district, a streak of quartz about 10 inches wide assays well.

The Paragon claim on Pritchard creek, east of Murray, is reported sold to Strobach & George of Spokane for $64,000 cash.

The Columbia mine, in the Buffalo Hump district, is locally reported sold to the Columbia M. Co., a Spokane corporation, for $2,000.

KANSAS.

At Ilioa the zinc smelters of W. & J. Lanyon are reported sold to the Palmyra Oil Co., the Kansas branch of the Standard Oil Co., for $2,000,000 cash. These are the largest natural gas smelters in the world.

MONTANA.

A former Austin, Nevada, miner, writing from Butte City, says: "We always thought that the Clifton tunnel was a bad place to work on account of giant powder smoke and bad air, but the Clifton tunnel was a paradise compared to the mines here. You fire your round of holes and back you have to go into the smoke; if you kick there is another miner ready to take your place."

The Union Placer Dredging & Refining Co. intends to construct ten dredges during the year on the Missouri river, according to S. F. Adams, the Gen. Mgr., at Helena. The company has been at work on the Missouri river near French bar building two dredges for securing the gold from the channel of the river, fifty men having been employed. The machinery is being put in place and the company wants to work through the winter, so that the machinery would be ready to be set in motion at the opening of spring. The dredges go in pairs, one of the boats carrying the dredging apparatus, to lift five cubic yards of gravel at once, and the other containing the gold-saving apparatus. The smallest of the boats is 100x40 feet in length and breadth. They draw 9 feet of water. "The company intend to put in ten such machines," says Mr. Adams, "and will before twelve months hence probably be employing 600 or 700 men."

The Parrot S. & C. Co. has recently been declaring a monthly dividend of 3%. The mines of the company are in good shape. There are three shippers, the Parrot, Belona and Original No. 6. Active development is also in progress at the Little Minah, the shaft upon which is down 800 feet. The Belona is the new shaft started last year west of the Moonlight. It is now developed to a depth of 600 feet and is said by the *Inter-Mountain* to be one of the richest copper mines in the district.

NEVADA.

Virginia *Chronicle*, Feb. 22: The draining of the Comstock flooded levels by the Risdon hydraulic pump plant is proceeding in a highly satisfactory manner. At 7 o'clock this morning Mgr. Ross sent the following telegram to the Pres. of the Comstock Pumping Association:

"Pump was shut down two hours last night due to a failure to properly regulate the surface water pressure. During this time the water rose 17 feet in the shaft. The pump was again started and at 7 o'clock A. M. the water was lowered 53 feet below the 1750 level and is constantly going down."

The flow being sent through the Sutro tunnel drain flume is nearly 6000 gallons per minute, and the thoroughness of the work of the Pumping Association in repairing the tunnel drain flume, under the supervision of Mgr. Ross, is demonstrated by the fact that its capacity for carrying off the water raised by the hydraulic pump is nearly double of what is required.

The following was received in San Francisco last Thursday afternoon:

VIRGINIA, Nev., Feb. 23, 1899.

Aug. Waterman, Sec'y Comstock Pumping Association, San Francisco: Water held at 53 feet below 1750 level. Are repairing pump compartment to receive the second elevator.

G. McM. Ross.

Taylor & Fulton have bought from the Amedee Borax Co. the borax marsh and works at Granite Point near the northeastern boundary of Washoe county. They are the principal owners of the Rose Valley borax marsh and works in Harney county, Oregon.

Tuscarora Chief is the title of a new mining company incorporated in Salt Lake, Utah. The property is the Eira mine of two claims at Tuscarora, which has produced considerable gold and silver. On the 200-foot level a raise is being made on a 2-foot body of high-grade milling ore, which carries with it a 9-inch stratum of rich ore, and, according to results obtained from the last consignment to Salt Lake, carries average values of 695.4 ounces silver and $157.60 in gold to the ton. The office of the company is in Salt Lake. The statement is made that a mill will soon be built.

Logan & Hully have returned to Dayton from San Francisco, Cal., where they purchased vats and other appliances for a cyanide plant to be erected in Como to cost $3500.

The last payment on the Young America mine at Tuscarora has been made and the property is now owned by the Young America M. Co.

At De Lamar the De Lamar Co. posted at the mine and mill notices that, if the eight-hour law passed, workmen would have to work for 30 cents an hour. The proposed law was defeated in the Legislature by a 2 to 1 vote.

The Pioche *Record* says A. Bybee of Chicago has bought the Great Eastern and Vesuvius mining claims in Bristol mining district for $10,000.

Virginia *Chronicle*: Stamps are again dropping in Six-mile canyon mills that were hung up during the cold wave on account of the freezing of their motive power, Six-mile canyon creek having been frozen nearly solid.

Hawthorne *Bulletin*: J. S. Cain and H. McCaghren have purchased the tailings at the Kinkead mill, and will put up a plant at once and begin cyaniding in the spring. It is estimated that there are about 2000 tons of tailings and that they will average $10 per ton.

Tuscarora *Times-Review*: The Dexter Co. has absorbed the Young America. The price is said to have been $6000. This must not be confounded with the Young America East. The new auxiliary hoist at the Dexter is a failure so far as hoisting with a cage and car is concerned. The engine is too small to raise the load and the cage has been discarded.

NEW MEXICO.

The output of the Hillsboro mines for the first six weeks of 1899 is reported at about 2000 tons.

John Leachman of San Francisco, Cal., is opening gold mines near Lordsburg.

Near Elizabethtown the owners of the Challenge at Hematite are running a tunnel which will cut the lead at a depth of 300 feet. This property has shipped some rich ore to the Pueblo smelter.

The Ajax mine and mill has been, by order of the court, turned over to the company. J. A. Wolcott now has charge. He will put in some new machinery and increase the number of stamps.

Advocate: Nearly 300 Hillsboro miners waited on the principal mine operators of the camp, asking for an eight-hour working day instead of ten hours, as at present. Their request was granted in a majority of cases, a few of the operators requesting further time for consideration of the matter.

OREGON.

(Special Correspondence). — At Cornucopia Jas. Arthur is arranging to save black sands from gravel.

Baker City, Or., Feb. 20th, '99.

A Youngston, Ohio, dispatch is authority for the statement that R. McCurdy, Pres. First National Bank, and J. C. Wyck, Pres.

Wyck National Bank, with others, have arranged to buy the Cornucopia mine, at Cornucopia, for $600,000.

Glass Bros. are in Baker City, Or., to make first payment on the Vaughan copper mine, Seven Devils district, on the Oregon side of Snake river, sixty-four miles from Baker City. They control the Peacock copper mine. They are completing a smelting plant in Basin, Montana. The copper ore from the Peacock, they say, will be transported by rail to the main railway line and by that road to their Montana smelter.

The Green Vale and Myrtle copper prospects in the Seven Devils copper camp, sold to J. Walton, formerly Supt. South Peacock, have been incorporated.

Near Baker City the just completed 300-foot tunnel in the Little Giant mine four miles from Red Boy has tapped a 4-foot vein.

Last week Mgr. Whittaker of the Eastern G. M. Co., owning the Balsley-Elkhorn mine, brought to Baker City $5000, the result of a mill run of seven days.

At Granite, on the Little Giant a 300-foot tunnel is completed, striking the vein at a depth of 100 feet.

On the Rising Sun, in the Bonanza district, a contract has been let to drive a 300-foot tunnel to tap the ledge. About 150 feet of this tunnel has been completed. It is Supt. W. L. Vinson's intention to build two mills on these properties next summer.

E. & E. mine output for 1898 was about $250,000.

The Baisley-Elkhorn mine, fifteen miles west of Baker City has sent down a bullion bar valued at $4500 as a result of one week's run.

The Bonanza is shipping ore regularly to Selby in addition to that treated at their mill.

SOUTH DAKOTA.

(Special Correspondence).—F. W. Bush, Mgr., and G. W. Tinsman, Supt. Vigilante M. & M. Co. of Custer, has returned from Denver, where he purchased from Hendrie & Boltboff Mfg. & Supply Co. a hoisting plant and other equipage for their property, comprising four claims, nine miles from Custer. In sinking a shaft to the depth of 104 feet and making crosscuts, they find their ledge of ore to be 60 feet wide near the surface and 114 feet wide at 100 feet depth. The ore, as per tests made, runs from 3% to 30% copper and from $1 to $8 gold to the ton. Their property is already provided with shaft house, assay office and residence buildings. The shaft will be sunk to a depth of 500 feet.

Near the Vigilante is the Wabash group of several claims. Under directions of Thos. Carroll, Sec. Wabash Co., a 300-foot shaft is being sunk. In the course of this work ores have been encountered averaging $75 per ton in gold. The property is to be equipped with hoisting machinery this spring.

The North Star, on the Penobscot, has a 165-foot shaft, all in ore said to average $45 per ton.

Judge A. T. Feay of the Custer County Court has several locations on the copper belt, near Four-mile, and is taking steps to develop them this spring.

Custer, S. D., Feb. 18th, '99.

UTAH.

The Alamo M. Co. purchasers, at Bingham, have made a payment of $1500. On April 1st another sum of $3500 is to be paid, and the remaining $11,000 is to be followed on July 1st.

When spring opens the Daly-West will build a sampling mill of its own and transport its crude ores and mill product from the mine to the railroad without the use of wagons. A tramway will be constructed from the mouth of the tunnel which runs from the Ontario mill to the mine, connecting at the 600 level to a point on the hillside below town; all hauling will be done over this tramway. As the 600 level of the Ontario taps the Daly at 800 feet and the Daly-West at the 1100, this appears to be a reasonable proposition, as all three companies will be benefited by it. This method of handling the output of the properties named will not only be an economical one, but it will be a sure safeguard against blocked roads and danger from snowslides in the winter time, and the latter features are no small consideration with mines located as are the Daly and Daly-West.

W. Quigley, Pres. Chicago Pumice Co. at Black Rock, tells the *Tribune* that orders are pouring in at the Eastern office so fast that they cannot get enough pumice to fill them. Mr. Quigley says he is going to leave orders to keep cars going East at such a rate that never again will the company be obliged to ho'd orders.

A one-third interest in the Highland Boy mine at Bingham is reported sold to the Standard Oil Co. for $4,000,000.

The *Tribune* reports a "boom" at Castle Dale, Emery Co., prospectors having made some discoveries of copper in the country south of there, the assay of which had shown $128 in copper besides good values in gold and silver. The new mines are thirty miles south of Castle Dale.

Salt Lake *Tribune*: Over 2000 samples of gold-bearing ore from the diggings of Central America have been delivered at the Butters laboratory in this city, and experiments to which they are to be subjected promise interesting results. Prof. Butters has found the southern Republics a most interesting field for some years and was so favorably impressed with one of the propositions that he purchased it. By chlorination he has succeeded in establishing an average of $22 gold per ton, while recent experiments have demonstrated that this may be increased with the aid of his personal discoveries. Recent experiments on local ores, especially those from the camps of Mercur, have satisfied Prof. Butters that temperature must in future be recognized as a most important quantity in the successful leaching of ores. He has found that with the use of hot water the per cent saved on certain classes of ore is astonishingly increased. It has not infrequently shown an increase of over $1 per ton. It has been notably effective in the leaching of ores with talcose gangue. Col. Hedron, to whom this information was addressed, agreed with him and as an example recited how readily the talc had disintegrated and surrendered its values when hot water was applied, while it had shown itself impervious to cold water. The colonel demonstrated this on the West Dip and at Bingham.

Mercur *Mercury*: The Antler property in the Lyon Hill country is looking particularly well. — The Lindar G. M. & M. Co. will be incorporated. A new steam hoist is being installed at the mines. — A new shaft is being sunk under contract on the Gold Cable.——The Mercur management are considering the advisability of installing either electricity or compressed air for motive power at the main shaft.

Tribune: A rich strike is reported on the 700 level of the Ajax ——The Northern Light tunnel is now in 400 feet; twenty men working.——The Horn Silver mine of Frisco is now shipping high-grade copper ores.——Good ore has been developed on the 430-foot level of the Hillside mine at Mercur.

WASHINGTON.

Men are working on the Lucky Choice claim on Gold Hill, four miles east of Republic. The shaft is down 30 feet.

The Little Falls mine on Douglas mountain, in the Okanogan country, has been purchased by a syndicate headed by F. Raborg of Republic.

The Republic M. Co. paid no dividend last month. The cold weather made it impossible to operate the mill at more than one-third its capacity during January.

The Sunset M. & M. Co. of Everett have completed the survey of their electric road from Index to Galena, and the power plant is new being installed at Sunset Falls, two miles below Index, on the south fork of the Skykomish river. The opening of this road will herald the working of shipping mines in the district.

The Everett *Independent* says, referring to the E. & M. C. Ry.: "Now that John D. Rockefeller has full control of the Monte Cristo mines, the road will be completed without doubt."

Spokesman-Review: The Iron Mask Co. at Republic is doing some surface work preparatory to sinking a shaft on the vein.——On El Caliph claim at Republic the work of development is being hurried forward.——The Morning Glory ledge, adjoining El Caliph, is also to receive immediate attention.——A rich strike is reported from the Insurgent mine at Republic.——The Republic is credited with having made another rich strike, the ore running $200 per ton in gold. It is said to fill the entire width of the drift.——The Lone Pine is developing a shoot of ore 12 feet wide, having an average value of $45 per ton.——The San Poil, in a raise from No. 2 to No. 1 level, averages $50 per ton and the Mountain Lion has 15 feet of $70 ore.——The Quilip has 6 feet of $35 rock.——At the Butte & Boston, Republic, a tunnel cut the vein 210 feet deep. The first assays in 33 inches of ore returned $8.50 per ton; but drifting north, the vein widened to the full width of the drift, with an increasing value in the ore up to almost $50 per ton.

WYOMING.

The mineral paint mines northeast of Rawlins will be reopened. Contracts have been secured for 10,000 tons of the ore to be shipped to Colorado.

FOREIGN.

AUSTRALIA.

Western Australia is reported to have produced 110,090 ounces of gold during January '99.

BRITISH COLUMBIA.

Crosscutting at the 100 level of the Victory-Triumph mine at Rossland has resulted in the discovery of a 2-foot vein of high-grade ore.

D. W. Moore, ore purchaser for the Trail smelter, says that the lead furnace of the Trail smelter will probably be blown in March 10th.

The Dardanelles mine, in the Slocan, is down 487 feet in promising ore.

The electric plant on the Iron Mask at Rossland was started this week and proved a success.

The shipments from the Last Chance mine in the Slocan average a carload a day and is locally reported to "net the owners a profit of $75 a ton over all expenses."

It is thought that the Minnesota Silver Co., operating the Ivanhoe property in the Slocan, will enter the Ivanhoe on the list of permanent shippers this spring. Last year upwards of $40,000 was spent in opening up the property.

At Kimberley the North Star M. Co. are working three eight-hour shifts in the large compartment shaft, now down 175 feet and in heavily mineralized rock.

T. R. More, Mgr. St. Anthony G. M. Co., is in Vancouver, returning from San Francisco, where he bought for the Omineca district machinery to the total value of $50,000.

The Toronto *World* says that the deal for the purchase of the Enterprise mine in the Slocan country by the British American Corporation is off. This deal was on for some time and was regarded as practically closed. The option recently expired. The Enterprise is on Ten-Mile creek, near New Denver.

Work is resumed in the Le Roi. Shipments have been resumed to the Northport smelter.

A large permanent plant is to be installed on the B. C. properties, Summit Camp, near Greenwood, to take the place of the small plant at present in use. It will be the largest in the Boundary country, consisting of a twenty-drill duplex air compressor of the piston inlet type, a double cylinder hoisting engine, a battery of 80 H. P., return tubular boiler, sinking pump, cage, etc., costing $20,000.

At Ymir the Blackcock mine, which had been making regular shipments to the Northport smelter for the past six months, has suspended further shipments.

Rossland *Miner*: British Columbia is becoming noted for its productive mines. The Province exacts a tax on the output of lode mines. The Minister of Mines recently made a return to the Legislature in compliance with a resolution requesting information as to the amounts paid by the several mines in the shape of a tax on their output. The ground covered in the reply is for the fiscal year ending June 30th, '98. The reply shows that official reports often are damaging to popular fallacies. It has been frequently stated that the Payne mine was the largest producer of values in British Columbia. The reply of the Minister of Mines does not bear out this assertion. It does show, however, that the Le Roi for the fiscal year mentioned above headed the list by paying $7525.45, against $6124.82 the previous year. Next in amount is the Payne, $5922.56, in '98, and $2409.04 in '97. The Silver King is third, $4411 and $2670.10. Then follow the Whitewater, $2398.28; Ruth, $2273.76; Reco, $1378.58; Cariboo Hydraulic, $1327.67; Slocan Star, $1299.93. These are all that paid in excess of $1000. There are eighty-five mines that paid less than $1000, the chief of which are the Idaho $898.81; the Cariboo (Camp McKinney), $840.50; No. 1, Slocan, $573.78; Last Chance, $541.91; North Star, $531.55; Enterprise, $491.14; Noble Five, $400.68; Iron Mask, $356.64.

Spokesman-Review: At Ymir, F. Davy has leased the Victor group on Wild Horse creek. The ore is said to be high-grade free milling quartz.——James Cronin, Supt. St. Eugene mine in East Kookenay, states that the property has recommenced shipping. The Lake Shore mine, near the St. Eugene, is also shipping regularly.——The owners of the Herald claim, at the head of Lime creek, have struck a ledge of Galena ore on this property. The work of crosscutting this newly found ledge will be continued until its width is ascertained.——The Pathfinder mine, fifteen miles from Grand Forks, has cut the vein in the crossout tunnel and has a body of copper sulphide ore.——At Grand Forks, while blasting on the grade of the Columbia & Western Railway last week, a ledge of copper ore was opened up on the Seattle, the width of which is claimed to be over 3 feet.——Work goes on on the Golden Eagle property on Volcanic mountain. This claim was recently bonded by an English syndicate for $35,000. It is a copper proposition.

COSTA RICA.

W. S. James of Gold Hill, Nevada, has returned after a year's absence in Costa Rica testing the mining property acquired there by Senator J. P. Jones. The property is a grant from the Government of that State and is in the mountain ranges twenty miles inland. Puenta Arenas is the nearest port. The property is known as the Mina La Union and has been prospected to a depth of 350 feet below the surface, developing a vein averaging from 15 to 20 feet in width, carrying gold values exclusively, the average being in the neighborhood of $10 per ton. A 40-stamp mill is being constructed near the mine to be operated by water power. About eighty men are employed in the development of the Mina La Union, to be increased when the stamp mill is completed. A majority of the employes are natives. The principal food is frijoles, tortillas, rice, eggs and beef, but no butter, the inhabitants being ignorant of that dairy product.

LOWER CALIFORNIA.

J. W. Dawson of Los Angeles, is at Cedros Island examining the gold mines there in the interests of W. A. Clark. It is understood that the latter has practically agreed to buy the stock in the mines owned by O. Schulenburg of St. Louis, amounting to 51%. The remaining 49% of stock is owned by several different parties.

Placer diggings are reported discovered eighty miles south of Calmalli, fifteen miles north of Ascuncion bay, about 400 miles south of San Diego. The diggings were discovered by Mexicans. Many miners from Calmalli and the surrounding country have gone to the new fields.

The Cedros island mines, located off the west coast of Lower California, about 400 miles below San Diego, are reported sold to W. A. Clark of Montana.

MEXICO.

F. McCann of the City of Mexico has a six months' option on the mines of A. Oest, Sierra Madre district, fifty miles from the City of Oaxaca, and will work the property.

C. W. Hayes has the Amarillas-Cajon and Yaqui mines, in the Cerro Colorado district near Santa Ana, Sonora. The two shafts, down to 200 feet each, will be sunk 250 feet deeper. The ledges in both mines are about 10 feet in width, and the ores run $8 per ton.

El Paso *Times*: S. C. Dunbar of Juarez and J. Palmer, in the Casas Grandes country, have secured a valuable silver mine thirty-five miles therefrom, near the Sierra Madre road. Assays show 700 ounces of silver to the ton.——A carload of valuable ore, which it is estimated will run 400 ounces of silver to the ton, has arrived over the Sierra Madre railroad from the Cinco de Mayo, or Top Summit mine, ten miles from San Pedro. The Pilares mining district, west of Casas Grandes, is expected to be a heavy producer this coming year.

ONTARIO.

The western Ontario gold fields are credited with having produced during January $105,900.

THE KLONDIKE.

The Dawson tramway is in successful operation. It runs from Dawson to the forks of the El Dorado and Bonanza creeks and up Bonanza, a total distance of nearly twenty miles. Thirty thousand dollars were expended in building the road and placing bridges over Bonanza creek. The company charges one cent a pound for all freight passing over the road. Ten dogs pull a sled load of 2000 pounds.

Klondike *Miner*: On 25 a pan containing $58 was taken out last week.——On 4, Lower El Dorado, a pan worth $100 was recently washed out ——A tramway has been started from the head of the left fork on Hunker over the divide into Lombard, to be operated by steam, and running shortly. —Bench claim of 21 Quartz, owned by five Swedes, is very good. They are getting as high as $1 67 to the pan. On Discovery they have also found good, but the benches, on the whole, are disappointing. On one lay on 3 Hunker they claim to have the richest dump there is thus far in the Yukon territory. Our informant says that it is his judgment that the dump at the present time will average $25 to the pan.—— No. 28, Gold Bottom, W. Canavan, layman, has put down three holes to bedrock, each hole averaging 30 feet, and very poor prospects thus far. There was another lay on this claim given up by the laymen. On the other hand, claims near the mouth of the creek are said to be turning out fairly well.

Commercial Paragraphs.

The Westinghouse Electric Co. has received a contract from the Mt. Whitney Power Co. of Visalia, Cal., for machinery and appliances to cost about $300,000.

The Black Warrior Copper Company signed a contract at Phœnix this week with the Colorado Iron Works for mining machinery, to be used at the Black Warrior mine near Globe. The contract calls for the shipment of the machinery at the end of forty-five days. The cost of the machinery at Denver is $30,000, and the shipping bill imposes an addition of over one-third of that sum. The appliances will completely equip the mine, including a smelter and leaching plant. The process will be of a capacity to reduce 150 tons of ore daily.

The Edward P. Allis Company of Milwaukee is building near Sorocco, New Mexico, a modern concentration mill for the Timber Peak Mining Company. The building will be a steel structure throughout and lighted by electricity. The equipment will consist of two 20x10 rock crushers of the Blake type, two sets of 36x14 and four sets of 30x14 Reliance rolls, four conical screens, two sets of hydraulic sizers, twenty 6-foot Reliance vanners. The mill is to be run by steam power, the equipment for which to consist of three 100 H. P. boilers and one 16x36 Reynolds Corliss engine. The machinery is on the ground and is now being put in place. Capt. Peter H. Scott, the veteran millwright, has charge of the erection for the Allis Company.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey, Strong & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING FEBRUARY 14, 1899.

619,461.—Sash Fastener—M. Angel, San Luis Obispo, Cal.

619,462.—Pruning Tool.—W. Ballerstedt, Altadena, Cal.

619,536.—Aerial Railway—J. Bond, Turlock, Cal.

619,538.—Gas Producer—Burch & Kasson, Seattle, Wash.

619,665.—Knee Pad—T. E. Bent, Los Gatos, Cal.

619,550.—Speed Gear—L. D. Ferris, Hood River, Or.

619,558.—Accordion—J. Galleazzi, S. F.

619,314.—Electric Heater—C. W. Jones, North Temescal, Cal.

619,495.—Valise—Miller & Nichols, Crockett, Cal.

619,341.—Rotary Separator—R. H. Postelthwaite, S. F.

619,502.—Lumber Raft—J. Poulson, Portland, Or.

619,346.—Automatic Damper—E. V. Rice, Azusa, Cal.

30,210.—Design for Game Board—Josephine Altshuler, New Whatcom, Wash.

Note.—Plain and Certified Copies of U. S. and Foreign patents obtained by Dewey, Strong & Co., by mail or telegraphic order. American and Foreign patents secured, and general patent business transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

Sash Fastener.—Myron Angel, San Luis Obispo, Cal. No. 619,461. Dated Feb. 14, 1899. This invention relates to a device for securing doors window sashes, making them absolutely tight in their frames, and means by which they can be instantly loosened so as to be opened or moved, and in the case of sashes they may be again locked firmly at any desired point. It consists essentially of slidable strips disposed in pairs having their contacting edges formed with inclined or serrated surfaces, means whereby one of the strips is held without motion in the channel in which the window is slidable, a toothed section on the other strip and a pinion engaging the same to operate the movable strip and lock or unlock the two, and pins fixed to the stationary strips extending through slots in the opposite strip, with springs on said pins adapted to retract the stationary strips and allow both to move in unison.

Books Received.

"*A Compendium of Gold Metallurgy*," by E. M. & M. L. Wade, Los Angeles, Cal., 125 pp., 12mo., giving a general idea of the scope and application of metallurgical processes used in extracting gold from its ores; 75 cents, postpaid.

"*The Speed Lathe, Part I, Advanced Metal Work*," by A. G. Compton and J. H. DeGroodt, 130 pp., a compendium of two years' work of students in the college of the City of New York; John Wiley & Sons, New York City, $1, postpaid.

Industrial Notes.

—Prescott, Ariz., wants to sell $75,000 water and sewerage 5% bonds.

—The Spring Valley Water Co. is credited with intention to put in a $450,000 filtering plant at Niles, Cal.

—The construction of the El Paso & Northeastern Railway from Alamogordo, N. M., to the adjacent coal fields, has commenced.

—President Graves of the White Pass & Yukon Railway states that the road will be built to Fort Selkirk, Yukon and also to Atlin.

—Preparations have been made by the miners of Sonora, Cal., and vicinity to have a celebration on the advent of the Sierra railway into that town.

—Cargo shipments of lumber to San Francisco from Oregon and Washington in '98 were 215,036,141 feet, 231,652,065 feet in '97 and 259,381,146 feet in '96.

—A Denver special says that railroad lines east of the Missouri river contemplate withdrawing all Western representatives, both freight and passenger, after March 1st.

—The O. R. & N. Co. is reported surveying a railway from Baker City, Or., sixty-four miles to the Seven Devils copper region, and the line, it is locally claimed, will be built.

—The American Steel & Wire Co. has added two new mills to its list of plants. One is the Puget Sound Wire Nail Co. at Everett, Wash., purchased of Rockefeller for $500,000.

—The Mexican Government has granted a privilege to dig for buried treasure in the streets of the City of Mexico. The Government receives one-fourth royalty should they find anything.

—In Seattle it is believed that the General Electric Co. is behind a syndicate of Eastern capitalists which is seeking to secure a franchise running for fifty years for a consolidation of all the street railways of that city.

—At Pine Grove, Cal., work on the Amador canal is in progress. The capacity of the canal at present is 2200 inches; after enlargement is completed, it will carry 3300 inches—1100 inches for the plant and 2200 inches for the mines.

—Denver reports a movement started looking to the consolidation of all the public utilities in the Colorado metropolis—a plan to combine street railways, water, electric light, coal, gas and telephone plants in one organization with $60,000,000 capital.

—Nevada hears that work of extending the Carson & Colorado road will shortly be commenced—an unlikely event. The road runs south to Keeler and is only 125 miles to Mohave, where it can connect with the A. T. & S. F., Atlantic & Pacific and Southern Pacific.

—Over $500,000 will be spent during '99 by the Chicago, Burlington & Quincy Railroad in improvements to its tracks, roadbed and bridges west of the Missouri river. Of this amount over $200,000 will be put into new iron bridges. One hundred and fifty miles of 75-pound rails will replace lighter rails, and 1,000,000 new ties will be put in.

—The Pacific railroads are paying their debts. The Union Pacific and Kansas Pacific paid what they owed the Government last year. The Central Pacific and Western Pacific have made settlement in twenty 3% notes, payable semi-annually. The indebtedness of these companies on the first inst., less the amount due from the United States, was $58,812,715.

—A contract was made last week, to run ten years, by which the Colorado & Southern Railroad secures trackage rights over the Union Pacific road between Denver and Cheyenne, thus enabling the Colorado & Southern to connect its Cheyenne & Northern branch with its other lines, and throws open to every line in Colorado a large and hitherto excluded territory.

—The Alaska Petroleum Co. has incorporated in the State of Washington. It is the belief of the owners of this property that, as soon as oil flows from the first well sunk, the stock will go to par, and this year. They claim that the crude petroleum has forced its way through the skin of the earth and stands in pools all over the hundreds of acres owned by the company.

—Japan reports an agreement concluded between the Morioka Emigration Co. and the agriculturists in Peru for the conveyance of Japanese laborers to the South American colony. The agreement having been approved by the Peruvian Government, the emigration company is about sending the first batch of laborers, 815 in number. The wages agreed on are $12.50 a month each.

—The Mexican Government has decided to offer a subsidy for the construction of a railroad across the backbone of the Sierra Madre range from Chuichupa, in the State of Chihuahua, to Huisopa, on the Sonora line. This road will save from four to five weeks' time in getting across the mountains. The Rio Grande, Sierra Madre & Pacific is to be extended from Casas Grandes to Chuichupa during the summer.

—Reports of a Pacific cable cause a New York paper to ask: "From where is the gutta percha for this gigantic cable to come? Every whisper of the construction of a transpacific line sends the gutta market at Singapore up by leaps and bounds. The ruling price of the gum is the highest that has ever obtained. It is stated, on what authority it is hard to say, that the visible supply of gutta is insufficient for the task and that if this cable is laid it will be the last—the last with a gutta percha insulation, at least."

—American machinery sold directly to consumers now tends to drive out all competition from Mexico; but it will be noticed that machinery houses keeping an office in Mexico themselves are doing better than those whose interests are entrusted to local commission houses or colonial merchants. Such machinery is sold very largely at the seller's terms, because as a rule the purchaser is an industrial or a foreign firm or corporation. But American heavy machinery constitutes only a small portion of that vast variety of industrial products upon which American superiority is resting and the use of which by the people has a tendency to raise the standard of living.

—At Stockton, Cal., the Blue Lakes Power Co. has strung its wire, and expects to turn in the first current of electricity from the mountains by May 10th. The Blue Lakes line is a novelty in electrical engineering. In the use of aluminum instead of copper wire to transmit the current, it has been a race between the Blue Lakes Co. and the Snoqualmie Falls Power Co., under construction in Washington, to see which would be the first to turn on the power through the white metal conduits. The California line will carry 30,000 volts. The aluminum wire, the first of its kind used on this coast, has reached Stockton. It is the intention to ultimately extend the line to Oakland.

—At Canyon Ferry, Montana, with little parade, electric power from the Missouri river dam near Helena has been turned into a network of wires extending in many directions from the dam site. The dam cost $500,000. Three million feet of timber, 45,000 cubic feet of earth and 12,000 cubic yards of granite were consumed in its construction. It is a little over 500 feet in length and contains four penstocks, each 175 feet long, having water wheels within them, revolving at the rate of 157 times per minute, furnishing the primary power to the generators. There have been installed four generators, with a capacity of 12,500 H. P., but as occasion requires this number will be increased to ten, thus supplying about 31,000 H. P. The generators employed are combined with a motor in the same instrument. They weigh fifty tons each.

—The Santa Fe R. R. Co. is substituting Japanese labor for white on track work between Mojave and Needles, Cal. The Randsburg *Miner* says the reason for this, the officials say, is that the supply of reliable white labor at $1.50 a day, the wages which the company have been paying section hands, is not equal to the demand. While there are hordes of so-called workingmen roaming the country and occasionally offering their services to the company as section hands, they cannot be relied upon. Usually these nomads leave after the first payday and new men must be employed. The Japanese, who are good stayers, work for $1.10 a day and make no trouble. The whites are still paid $1.50, but none are employed unless they give assurances that they will continue in the employ of the company long enough to be of some service. Officials of the road say they do not discriminate in favor of Japanese except where forced to do so.

—J. A. Scrymser, president Pacific Cable Co., says: "The situation in the East is not at all bright so far as a new cable is concerned. An absolute monopoly over the Philippines is held by strong English companies in the East. Their monopoly also extends to Hongkong and the Asiatic coast, including Corea. The Great Northeastern Co. enjoys the same privileges between Japan and the Asiatic coast. Exclusive rights living until 1940 are held by this company. The Japan contract will expire in four years, but an extension of fifteen or twenty years has just been arranged for. Unless an arrangement is made with these companies it would be very difficult to land an American cable either in the Philippines or on the Asiatic coast. These companies hold exclusive or vested rights. Private capital will be very slow to risk success under such a condition of affairs. To force a cable landing would mean the expenditure of a considerable amount of money. The United States will be unable to abrogate them without paying heavy compensation."

—The following is a report from a representative of the Philadelphia Commercial Museums in Mexico upon the increasing use of gas and gasoline engines and electricity for power purposes: "What is most needed in Mexico at the present time in order to assist in properly developing manufacturing and mining resources is cheaper power-supplying fuel. Coal is nearly all imported and costs from $6 to $8 in gold per ton, according to distance from the coast, and water in all sections is too scarce to supply power. The total imports of coal in August were $85,725 gold. In some sections water costs as much as $1.50 per thousand gallons. Statistics do not show the number of gas and gasoline engines imported, but it is well known that very few have entered the country, and of this most are of the hoisting engine type for mine work, etc. Wherever used they are well liked and the demand is increasing. Very few of those here came from the United States, most of them being from Great Britain and Germany. The use of gasoline engines is bound to increase rapidly, so to introduce American engines it would not be necessary to attempt take established trade away from other houses. The total foreign trade of Mexico now amounts to about $100,000,000 gold annually, and her imports of all classes of goods are increasing at the rate of $5,000,000 gold a month. The next few years will be the most prosperous that Mexico has ever experienced. The country is now in the midst of an era of development such as it has never witnessed. New industries are being established and old ones are branching out, and steady development is the order of the day. There is no 'boom' here, and no one wants one. Every month some new railroad or extension opens up new territory, stimulating it to greater production and bringing new markets to the outer world. Were American manufacturers of gas and gasoline engines to appoint responsible agents in Mexico City, Guadalajara, etc., furnish them with modern samples and catalogues, printed in Spanish, a good trade would probably be the result."

Personal.

P. H. DEIDESHEIMER is in Inyo Co., Cal., examining copper mines.

T. L. AYRES has returned to Cerbat, Arizona, from Oakland, Cal.

CLARENCE KING is examining the Center Star mine at Rossland, B. C.

W. A. ROBERTS of El Dorado county is in San Francisco on mining business.

W. H. TRUESDALE is to have $40,000 annual salary as Pres. Lackawanna Railroad.

F. WILMANS, a prominent mining operator of Tuolumne county, is in San Francisco.

W. F. DETERT, Supt of the Zeila mine at Jackson, Amador Co., is in San Francisco, Cal.

W. FRANK DRAKE, Sonora, Cal., has been appointed Supt. of the San Guiseppi mines there.

W. A. KING, Montana's new U. S. Senator, is examining mining property on the Mexican border.

THOS. R. STOCKETT of St. Louis, Mo., has been appointed Gen. Mgr. Pacific Coast Co.'s coal mines.

HENNEN JENNINGS has returned from South Africa and has taken up his residence in San Francisco, Cal.

R. H. CAMPBELL of Shasta has returned from California to the Horsefly, Cariboo, B. C., to resume work on the Horsefly hydraulic mine.

M. MARKS is in San Francisco from Dawson to get thawing machines such as, he says, are being successfully used there thawing 10 feet per day.

S. HEIN and F. Calmer, two Russian mining engineers from Siberia, are in San Francisco, en route to New Zealand to examine extensive dredging operations.

R. J. ANDERSON of Boise City, Idaho, Mgr. of the Twin Springs mines, illustrated and described on page 201 of this issue, is at Colfax, Cal., arranging for miners from Dutch Flat and vicinity.

W. B. PARSONS, now making a survey for an American railroad through China, cables success in securing mineral rights in that country. C. Cary, a member of the syndicate, started from New York City for China last week to investigate the value of the mining franchises.

GEN'L MGR. VAN ETTEN of the New York Central railroad, and president of the Randsburg, Cal., railway, is in San Francisco. He is reported to have said that "without doubt at least one line of railroad will be built immediately from southern Nevada into southern California."

L. W. MORGAN of Los Angeles, Cal., has assumed the management of the Azurite copper properties near Tucson, Arizona. The smelter is turning out copper matte; fifteen men are employed. Saeger, Cooper & Fellows of the Calumet & Hecla Copper M. Co. of Michigan paid $50,000 for the property last December. It is locally stated that the properties will be fully developed and a large plant established.

W. J. NEVIN, Gen. Mgr. California Southern railway, is in San Francisco. Regarding the construction of the S. F. & S. J. Valley road, he says, if the present progress continues, it will be possible to have the trains of the Santa Fe system running to Point Richmond by Sept. 1st, '99. It is probable, however, that the regular transcontinental service will not be inaugurated by the Santa Fe until Jan. 1st, 1900. Wm. Bissell will take charge in San Francisco as Asst. Traffic Mgr. of the Santa Fe.

JOSEPH MCGILLIVRAY, a veteran California miner, has returned to San Francisco from Dawson. He says there are enormous areas of low-grade alluvial gravels in the Yukon region, but as it will cost $3 to get $4 worth of gold the gross output must be taken off before work can be profitable. Mr. McGillivray is going to Ottawa to try and get the Government to take off the royalty. He has a proposal to make to the Government, he says, covering the whole matter of working these deposits, and he wants to get concessions so as to be able to raise money in England.

OLAF ELLISON, special representative for the Pacific coast to the Paris Exposition, is in Los Angeles, Cal. He says the Paris Exposition is expected to be opened early in 1900. The space officially allotted to the United States has been nearly doubled, being now 220,000 square feet of floor space—about one-half of that at the Chicago Exposition. United States Commissioner General Peck has appointed J. V. Skiff of Colorado chief of the mineral department. The Paris Exposition headquarters are at the Auditorium in Chicago. Of the space allotted to the United States, that devoted to mines and metallurgy is 7700 square feet; to machinery and electricity, 48,000 feet; to civil engineering and transportation, 16,000 feet. The limited space allotted makes it imperative that quantity give place to quality in the selection of exhibits.

THOS. J. BARBOUR has returned to San Francisco from Virginia City, Nev., where he has been representing the Risdon Iron Works of San Francisco, Cal., who placed the big hydraulic pumps in the C. & C. shaft of the Comstock lode. He reports progress thus far as more rapid and satisfactory than had been anticipated. On the morning of Feb. 23 the water was lowered 81 feet below the point of discharge, which is 29 feet above the 1750 level. The pumps are in the central (a hoisting) compartment at present, and as the water is lowered the old pump rods, column pipes, etc., have to be cleared out of the pump compartment to make room for the hydraulic machinery. At the rate of unwatering the shaft thus far it is evident that for a time the rate of progress will exceed the inflow of water from distant connections. Mr. Barbour and Mgr. G. McM. Ross are each very hopeful of the ultimate result of the undertaking. The flume in the Sutro tunnel has been repaired under the direction of Mgr. Ross, and is now carrying 6000 gallons of water per minute, with a capacity of double that amount. There has been a slight delay owing to an unequal pressure in the pressure column, but steps have been taken to make this constant. During the progress of the work careful observations will be made at other shafts in neighboring mines to note the effect the draining of the C. & C. shaft has at these points.

Recently Declared Mining Dividends.

Parrott S. & C. Co., Montana, 3%, $69,000; Feb. 18. Total to date, $2,276,898.

Cariboo, Camp McKinney, B. C., 1½ cents per share; Feb. 20.

The Homestake M. Co., South Dakota, usual monthly dividend, 25 cents, and an extra dividend of 25 cents; payable Feb. 25.

Gold Coin, Colo., 1 cent per share, $10,000; Feb. 25.

National Lead Co., regular quarterly dividend, 1¾%, on its preferred stock; payable March 15.

POSITION WANTED by experienced cyanide man as superintendent of a mill or as assayer and chemist. Technical graduate. Will take charge of a cyanide proposition for a small salary with a percentage of the profits. Address S. C. M., care of Mining and Scientific Press, San Francisco, Cal.

WANTED.—Millman thoroughly understanding concentrating and amalgamating by stamps or Huntingtons, all latest methods known, desires position at an early date with some reliable company in U. S. or out. Best of references furnished. Address K. W. A., this office.

WANTED—SITUATION BY A PRACTICAL MILLMAN AND ASSAYER.

Would go anywhere. Best of reference. Address F. B., care of Mining and Scientific Press.

WANTED—POSITION BY A CHEMIST, ASSAYER and MINING ENGINEER.

Cyanide a specialty. Speaks Spanish. First-class references. Address Box 28, this office.

WANTED—ASSAYER AND ANALYST DESIRES POSITION.

Experienced and reliable. Excellent references. Address COMPETENT, care of Mining and Scientific Press.

WANTED TO BUY—AN ASSAY OFFICE OR CHEMICAL LABOBATORY, or would purchase an interest therein. Experienced in all branches of inorganic and organic analyses. References exchanged. Address Chemist, this office.

WANTED.

Capital to Handle Extensive Gold Mines.

JAMES ARTHUR, Cornucopia, Oregon.

WANTED.

Position as Superintendent or Assistant Superintendent of Copper Mining and Smelting Works.

Competent Smelter, Assayer, etc. Understands handling men; speaks Spanish; willing to go to Mexico or South America; best references. Address COPPER, this office.

..CRIPPLE : CREEK..

FOR SALE—CYANIDE PLANT,

100 tons daily capacity; in first-class condition to handle Cripple Creek ores.

Plant in full running order, with all latest improvements. Address JOHN S. MACBETH, Equitable Building, Denver, Colorado.

DIAMOND DRILL

FOR SALE,

OR CAN BE HIRED, TOGETHER WITH EXPERT TO OPERATE IT.

Apply to J. A. MURRAY, care of Risdon Iron Works, San Francisco.

Silver City Reduction Co.,

SILVER CITY, GRANT COUNTY, NEW MEXICO.

Purchasers and Smelters of Gold, Silver and Copper Ores.

This Plant is Owned and Operated by the Estate of the Late Senator George Hearst of California.

Utah Mines.

The Utah mining camps are fast forging to the front. THE TINTIC DISTRICT, BINGHAM, PARK CITY, MERCUR, LA SAL AND GOLD MOUNTAIN are all located on the line of the

RIO GRANDE . . .

WESTERN RAILWAY.

Two trains daily from Denver via Denver & Rio Grande or Colorado Midland and RIO GRANDE WESTERN. For pamphlets, etc., write

F. A. WADLEIGH,

General Passenger Agent, SALT LAKE CITY.

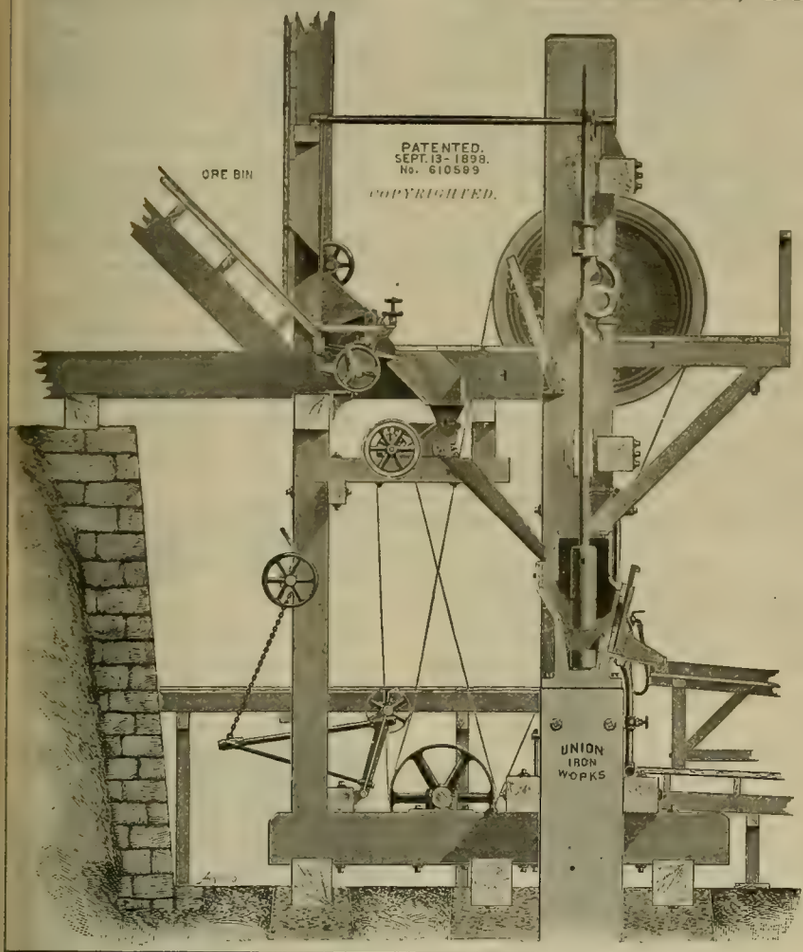
MICHIGAN COLLEGE OF MINES.

Supported by the State of Michigan. Practical work. Elective system. Special advantages for men of age and experience. For catalogues address

DR. M. E. WADSWORTH, President.
Houghton, Michigan.

UNION IRON WORKS,

222 Market Street, San Francisco, Cal.



THIS ILLUSTRATION

Shows our patent Improved Stamp Mill, with Secondary Crusher, which increases the capacity of the ordinary stamp battery from 25 to 30 per cent.

We respectfully invite the attention of those contemplating the erection of new mills to this practical improvement.

For particulars address

UNION IRON WORKS,

222 MARKET ST., SAN FRANCISCO, CAL.

Westinghouse

Generators and Motors

for direct and alternating current. Our Type "C" Motor is especially adapted to driving factory machinery, as there is absolutely no danger from fire risk. It is simplest to operate of any motor in existence.

THE BRYAN ROLLER QUARTZ MILL.

We are the sole manufacturers of this Mill. A test made by the Bullion-Beck Co. of Eureka, Utah, with this and the Huntington Mill proved conclusively every claim we made for the Bryan Mill, viz: that the Bryan would crush more ore with less repairs, less power and less slimes than any Mill made. Result—they are now operating three of the five-foot Bryan Mills and find them superior and more satisfactory than any Mill they ever used. L. C. Trent & Co., who had formerly sold the Huntington Mill, immediately manufactured a Mill infringing our patent. Suit brought in the U. S. Court resulted in a verdict in our favor, and we shall prosecute to the full extent of the law any infringement of any character whatsoever in the MAKING, USING or SELLING of the same. : : : : : : : : : : : :

Strong.
Economical.
Simple.

MANUFACTURED BY

The BRYAN MILL is constructed on the principle of the Chili Mill, except it has three rollers arranged to run in a continuous discharging pan. It crushes either gold or silver ores. It consists of an annular cast-iron mortar with fixed steel dies arranged in the path of its three crushing rollers. Power is applied direct from a pulley through a bevel gear and pinion secured to stationary center post. We present a few of many advantages it possesses over any other Mill: Larger screen capacity and free discharge. Amalgamates a larger percentage of gold. Quickly and cheaply erected; with regular feed and proper flow of water requires little attention. Crushes hard or soft ore with smaller amount of power per ton and less wear and tear of machinery. : : : :

Send for Catalogue No 8.

Effect a Saving in Friction Losses. No Trouble to Install. No Alterations of Mill Necessary. No Keys or Wedges to Adjust.

Manufactured only by GLOBE IRON WORKS, STOCKTON, CAL., U. S. A.
Manufacturers of All Classes of Mining Machinery. Estimates Furnished.

OFFICE OF WILDMAN GOLD MINING COMPANY. SUTTER CREEK, CAL., June 28, 1898.

Globe Iron Works, corner Main and Commerce Streets, Stockton, Cal.—GENTLEMEN: Replying to your inquiry about the Globe Patent Battery Stem Guides furnished us by you last fall, will say that you supplied us with Guides enough for ten stamps of the Wildman Mill. These Guides have been in constant use for the past eight months, and so far **do not show any wear either on the Guides or the Stems.** They are more convenient than any Guide I ever handled, and much time is saved with them in changing stems, etc. The Guide can be set so close you always get a fair blow on your dies, and the use of these Guides materially increases the crushing capacity of your batteries. **It is our intention to replace all of our Guides with those of your make,** and I cheerfully recommend them to any one desiring a good, serviceable and economical Guide. Very truly yours. JOHN ROSS, JR., Superintendent.

WOODBURY'S IMPERIAL CONCENTRATING TABLE.

THE Imperial Concentrating and Amalgamating Table is the latest invention of Mr. Geo. E. Woodbury, whose fame as one of the pioneer concentrator builders is world wide, machines of his manufacture being in general use in every country on the globe where the milling of ores is carried on. This Table is, however, built on entirely new lines, differing materially from either the well-known belt or bumping table types of concentrators.

SIMPLE IN ITS CONSTRUCTION.

SAVES FINE SULPHURETS.

WITHOUT LOSS IN TAILINGS.

MAKES HIGH PRODUCT.

CAPACITY FROM 5 TO 10 STAMPS.

Mining and Metallurgy.

The latest and best books can be had from the Book Department of the MINING AND SCIENTIFIC PRESS at best prices. ALL BOOKS SENT POSTPAID. Following is a partial list:

ASSAYING:—PART I—GOLD AND SILVER ORES.
Third edition; Rewritten and Improved by the Author, C. H. Aaron; 130 pages, illustrated....$1

ASSAYING:—PARTS II & III—GOLD AND SILVER BULLION, LEAD, COPPER, TIN, ETC.
Latest edition; 161 pages, illustrated, cloth. Much of the original text replaced by new matter.....$1 75

PROSPECTOR'S FIELD BOOK AND GUIDE:
By H. S. Osborn.....$1 50

ROASTING OF GOLD AND SILVER ORES AND THE EXTRACTION OF THEIR RESPECTIVE METALS WITHOUT QUICKSILVER:
Second edition; Guido Kustel, M. E.; 156 pages, with illustrations of furnaces, supplements and working apparatus.....$3

PRACTICAL TREATISE ON HYDRAULIC MINING:
By Aug. J. Bowie, Jr. On the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on heavy grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc.....$5

PRACTICAL HYDRAULICS:
A book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers and Irrigators. By P. M. Randall. Contains useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulæ, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules and tables are prepared. Is specially applicable to the Pacific Coast.....$2

MODERN COPPER SMELTING:
E. Dyer Peters, Jr. Eighth edition. Rewritten and enlarged. Profusely illustrated.....$5

STAMP MILLING OF GOLD ORES:
By T. A. Rickard, M. E. An actual record of milling practice in this and other countries. Deals with the erection and management of mills, and contains many helpful suggestions. Well illustrated. Cloth.....$2 50

MINERS' POCKETBOOK:
A reference book for miners, mine surveyors, geologists, mineralogists, millmen, assayers and metallurgists. By C. G. W. Lock. 472 pages, illustrated, flexible leather.....$5

MANUAL OF MINING:
For the use of Mining Engineers and Technical Schools. Treating of Preparatory and Exploratory Work, Methods of Mining, Hoisting Machinery, Pumping, Ventilation Shafts, Tunnels, Blasting, Timbering, etc., etc. By Prof. Magnus C. Ihlseng, E. M., Ph. D. Third, revised and enlarged, edition. 548 pages, 8vo., cloth.....$4

THE EXPLORER'S AND ASSAYER'S COMPANION:
Third edition. By J. S. Phillips. A practical exposition of the various departments of Geology, Exploration, Mining Engineering, Assaying and Metallurgy. An exceeding valuable work.....$6

THE METALLURGY OF GOLD:
By M. Eissler. Profusely illustrated.....$5

CYANIDE PROCESSES FOR GOLD AND SILVER ORES:
By E. B. Wilson, E. M.....$1 50

SKELETON MINING REPORT:
Of great practical value to miners and mine owners in making a comprehensive report on mining properties. Useful and convenient to mining engineers as a field notebook. Price, postpaid.....50c

P&B BUILDING PAPER

The walls of a house are built for protection. If the sun and weather open up the sheathing, the rain or the air will get in and cause discomfort and doctor's bills. To prevent this the architect or builder uses building paper. There are many kinds, but only two classes—the poor and the good. P & B PAPER is good—the best. It is very strong, odorless, waterproof and airproof, and will not rot. Ask your dealer for samples, or write us for them. We are the makers.

PATENTS

DEWEY, STRONG & CO'S
PATENT AGENCY.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American reports, with full copies of U. S. Patents since 1872. All worthy inventions patented through DEWEY, STRONG & CO.'s Patent Agency will have the benefit of a description in the *Mining and Scientific Press*. We transact every branch of patent business, and obtain patents in all countries which grant protection to inventors. The large majority of U. S. and foreign patents issued to inventors on the Pacific Coast have been obtained through our agency. We can give the best and *most reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and circulars free.

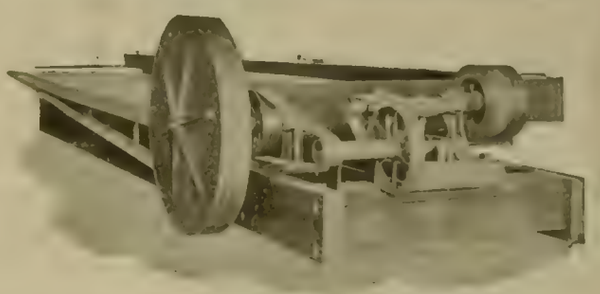
Sole Pacific Coast Agents and Builders of the Celebrated

WILFLEY CONCENTRATOR.



The Wilfley Table is fully covered by U. S. patents Nos. 580,338 and 590,675. Infringements will be prosecuted to the full extent of the law.

PRICE, $450, F. O. B., San Francisco.

One of these machines will take the place of two or three belt concentrators of any style and do very much better work.

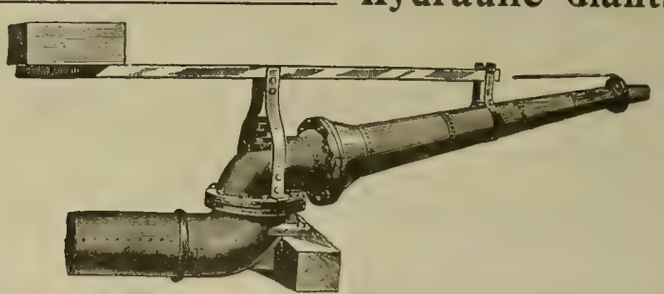
Some Practical Reasons Why the Wilfley Concentrator Should Be Used in Gold Mills:

1. It will successfully handle three or four times more material than any belt Concentrator made, without exception.
2. It will save more sulphurets in proportion while so doing, and catch any float gold, amalgam or quicksilver which may escape from mortars or plates.
3. It will make cleaner and much more valuable concentrates, thus saving useless expense for transporting valueless material, as also extra cost for treatment.
4. It requires little or no attention when once adjusted and no expert is required to either adjust or run the machine.
5. It will save much expense in power and room, and the first cost of a mill requiring concentrators.
6. It has no expensive belts to crack and wear out, nor complicated machinery to keep in repair.
7. It is the only sensible plan of concentration, as any kind of material can be worked, which is not true of any style of belt machine.

—— SEND FOR CIRCULARS. ——

These Machines are Kept in Stock Ready for Immediate Shipment.

Double-Jointed Ball-Bearing Hydraulic Giants.



The above presents an improved **Double-Jointed Ball-Bearing Hydraulic Giant** which we build. The improvement consists of the introduction of a **Ball Bearing** by which the pressure of the water is reduced to a minimum and the direction of the nozzle changed at will with ease.

Catalogues and prices of our specialties of HYDRAULIC MINING MACHINERY furnished upon application. **JOSHUA HENDY MACHINE WORKS, 38 to 44 Fremont St., San Francisco, Cal.**

Market Reports.

The Markets.

SAN FRANCISCO, Feb. 23, 1899.

SILVER. — London, 27¾d; New York, 59⅛; San Francisco, 59⅛; Mexican Dollars, 47⅛@48. New York exchange, sight, 17⅛; telegraphic, 20 cents premium.

LEAD. — New York reports "barely steady," $4.40 bid, $4.45 asked; brokers' price, $4.20.

Local, pipe, 7@7¼c; sheet, 7@8c; pig, 6¾c; bar, 7c.

COPPER.—New York reports Lake quiet and unchanged, $17.75 bid, $18 asked. Local, bar, 21¼c per lb.

It has been claimed that 18c for copper is an extreme, and that as one extreme follows another, copper at 8 cents may now be expected. Statistics of the copper market for the past thirty years do not prove the assumption that 18c is an extremely high price. The average price of copper in the ten years that ended with '98 was exactly 11⅞c, the lowest price reached in that period being 9.35c. In the preceding twenty years, ending with '88, the average price was 19 27c, the lowest being 10c, and the highest being 45c. It is apparent that the extremes were reached when the metal sold at 9.35c and 45c, and that the mean average must be somewhere between 11⅞c and 19.27c.

Extremes do not necessarily follow one another in the price of commodities. Because within the present century the value of timber, coal, petroleum and many other things was not known, it does not follow that they will again be worthless. New uses make new prices for commodities, and the many new fields into which copper is introduced, and its enlarged consumption in those branches of industry where it has always been used, assure an increasing demand for a long time to come.

It is probable that present prices will have some tendency to curtail the consumption, while the production of copper will increase slowly, and that the price will eventually settle to a lower level. At the present time, however, it is impossible to figure out from where the copper is coming to supply the present demand and stop the rapid decrease of the visible supply.

IRON.—American, soft, $22@24 per ton; Scotch, $27. Local bar, 2¼c per lb.

The *Iron Age* says: Steel is exceedingly scarce for prompt delivery, $18 50 in the central West and $21 in Philadelphia. Manufacturers of merchant pipe have advanced prices 5%.

SPELTER.—10¼. Official statistics of the production of spelter in the United States for the calendar year 1898, as compiled by Special Agent C. Kirchhoff, of the Geological Survey, show a total of 115,399 short tons, an increase of 15,419 tons over 1897. The aggregate is distributed as follows: Eastern and Southern States, 8631; Illinois and Indiana, 47,103; Kansas, 40,132, and Missouri, 19,533. The greatest increase in output was in Illinois, Indiana and Kansas. The exports of ore and spelter for the first eleven months of the year were: Ore, gross tons, 10,254, $291,870; spelter, net tons, 9535, $937,631. This indicates a considerable falling off in '98.

TIN.—Pig, 30c per lb.; Bar, 29c. New York reports "strong and scarce" at $24.25.

ANTIMONY.—16.

BABBITT METAL.—No. 3, 8c.

QUICKSILVER.—Local, $42; export, $39.00 @39 50; carload lots, special rates.

POWDER.—F. o. b., San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15¼c; less than one ton, 17¼c. No. 1* 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2* 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

FUSE.—Triple tape, $5.10 per 1000 feet; double tape, $4.35; single tape, $3.45; Hemp, $3; Cement No. 2, $4.35; Cement No. 1, $3.45.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9.

Hercules Gas Engine Works, San Francisco, Cal.

DEAR SIRS:—

The fifteen-horse power gasoline engine and hoist purchased from you is doing fine work and is perfectly satisfactory in every respect.

Yours truly,

TUOLUMNE MOTHER LODE M. & D. CO.,

Per N. W. Moodey, Pres.

We have two large books full of testimonials; they speak better for the HERCULES than we can. Our works are the largest in the country. We have built and sold over 3500 engines; they are the standard everywhere. Any size up to 200 H. P. Stationary, Hoisting and Marine.

Assessment Notices.

JUNCTION MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Tuolumne County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 4th day of February, 1899, an assessment (No. 23) of three (3) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, 106 Leidesdorff street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 14th day of March, 1899, will be delinquent and advertised for sale at public auction, and, unless payment is made before, will be sold on MONDAY, the 3rd day of April, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CALVERT MEADE, Secretary.

Office—106 Leidesdorff street, San Francisco, California.

ORLEANS MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Grass Valley, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 8th day of February, 1899, an assessment (No. 8, new series) of seven (7) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 324 Pine St., San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 14th day of March, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 5th day of April, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

GEO. P. THURSTON, Secretary.

Office—324 Pine St., San Francisco, California.

UNFAIR COMPETITION.

Our recent announcement that inferior goods had been sold and billed on the coast as our goods, and that our trade-mark numbers had been counterfeited, has disclosed an even greater extent of these practices than we had supposed to exist. To make the resulting damage to the reputation of our goods as small as possible and to protect our would be patrons we repeat:

All our catalogue goods, except those listed by us as manufactured by others, are stamped with our name "Keuffel & Esser Co." or our initials "K. & E. Co" and where there is room for it, with our trade mark 
Our German drawing instruments bear only the trade marks or

We never stamp our goods with catalogue numbers only, and goods so stamped are therefore not ours. All our goods are fully warranted to conform to the description we give of them in our catalogue and to be of the quality and grade specified. We make some lines of cheaper goods for the jobbing trade, but they differ from our catalogue goods in quality and appearance. These inferior goods are not stamped with any of our trade marks. Our catalogue goods are not furnished to any dealer or agent without our complete stamp as described above, and any claim that we furnish our catalogue goods by special arrangement without our stamp is therefore an attempt to deceive. Our special papers in rolls or sheets

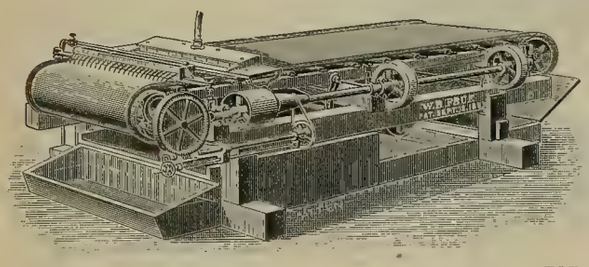
Duplex Universal Anvil Paragon Normal

are watermarked or stamped along the edge with their name. Any claims that our papers are furnished by us in bulk without these names or that these papers have been obtained otherwise than through us, are absolutely false. We will thankfully accept any information bearing on the counterfeiting of our trade-mark numbers or the palming off of other goods as ours.

Very respectfully, KEUFFEL & ESSER CO.

FOUR and SIX-FOOT FRUE VANNERS

With Brownell "Patent Lip" Flange Belts.



STANDARD MACHINE OF THE WORLD.

When a Concentrator like the Frue Vanner has been on the market nearly two decades, and the sales have constantly increased, it is safe to say it is the "Standard Machine of the World." More Frue Vanners have been sold during the last twelve months than for the same period at any time during the history of the machine. Practical mining men in all parts of the world where mining is carried on will testify as to its merits. It is the "standard" which all competitors are trying to imitate.

The results obtained by this machine are the "acme" of concentration, and several cheap and untried machines that have lately come on the market compare by it. The manufacturers will tell you that they are "just as good, and cheaper," etc. The facts are that no other concentrator made has an equal capacity, or will yield as clean a concentrate with as small loss in the tailings as the Frue Vanner. The amount saved from the lower first cost of an inferior machine counts little in the year's results, when compared with the increased output from a Frue. This machine not only gives better results at both ends of the belt (i. e., clean product and poor tailings), but is operated at less expense and requires less attention than any other machine on the market. At the Alaska-Treadwell mine, where they have ordered over 350 Frue Vanners, one man attends 48 machines for 12-hour shift.

Prospecting for Gold With a Drilling Machine.

ritten for the MINING AND SCIENTIFIC PRESS by ROBT. H. POSTLETHWAITE.

I will briefly describe the method of prospecting r gold in placer deposits by means of a drilling ma- ine. I have been interested in gold dredging for any years past and have, after considerable expe- ence, come to the conclusion that the business can, y thorough and systematic prospecting beforehand the ground on which the dredge is to operate, be moved from the sphere of uncertainty and specu- tion and be rendered a profitable and safe invest- ent. The old method of prospecting by the sinking shafts was so costly that but few felt inclined or, deed, were able to thor- ughly prospect a piece of round before operating e same by means of a redge. In consequence of is fact many dredging perations have proved ilures and the dredging usiness has received a ack eye, not from any in- rent fault in the dredge t because the values were t in the ground. After oroughly investigating fferent driller and other achines, I, in April last, rchased a Keystone No. driller for the purpose of rospecting certain placer aims upon which I medi- ted placing a dredge. I first felt dubious as to hether it was possible to tain by means of a driller thorough and accurate st of the values in any rticular piece of ground. nce purchasing the above entioned machine I have rospected hundreds of res by means of it and n now convinced that the roblem of thoroughly and stematically prospecting dredging ground at a asonable figure has been solved. In order to test e accuracy of the prospect obtained by the driller, sank a shaft close to the driller hole and obtained a sult almost identical. The driller showed 37 cents d the shaft 35.8 cents to the cubic yard, and in the tter was a large boulder which would account for e slight difference in value of the two prospects. ll that is necessary to insure success is the exercise great care both in the drilling and in the handling the sand pump.

DRILLER IN OPERATION NEAR FOLSOM, CAL., SHOWING MR. POSTLETHWAITE AND MEN WITH NO. 2 SELF-MOVING RIG.

The driller is a traction machine of 8 H. P. and ay be described as a combination driller having th "mast" and "walking-beam." The hole is illed by means of a heavy steel bit attached by a per screw to a 24-foot stem weighing some 500 unds. This stem is attached to a hempen cable nning over a pulley at the top of the derrick and wn to a drum on the body of the machine. The aterial is raised from the hole by means of a vac- m pump. The machinery is set in motion and the t and stem are by means of the cable raised from inches to 36 inches, according to the stroke used (which can be regulated at pleasure), and then let fall their full weight. The fall or stroke is regulated by a crank which gives motion to the walking-beam from which the drilling tools are suspended. Without delay the drill is raised for another stroke and during its ascent the operator twists it about one-eighth of a turn, so as not to strike two successive blows in the same place, otherwise the second blow is lost. During this process water must be put in the hole, about two gallons to each foot drilled, so that the cuttings may take the form of batter or thin mortar. When the depth of the hole made is such that the cable prevents the drill from striking the bottom of the hole with its full force, by means of a brake an inch or so of cable is allowed to run off the reel or drum, and the process continued until the cut-up clay, rock or gravel becomes so thick that the drill will not fall freely through it. When about 2 or 3 feet have been drilled the drill rope reel is thrown in gear and the tools lifted from the hole by means of the engine. The brake holds the drill suspended in the derrick, when the drill rope reel is thrown out of gear and the sand pump reel is thrown in gear. The sand pump is then lowered into the hole by means of a brake. The cuttings in the form of mud or mortar enter the pump at the lower end and a valve prevents them from flowing out when the pump is raised. The sand pump is drawn up and emptied two or three times, until all loose material has been drawn up. Great care must be exercised in preserving all the material drawn up, as on this depends the accuracy of the prospect. I empty the material into a large bucket or tub and keep a Chinaman continually panning it out. The amount of material is small, as the hole only measures 6 inches in diameter. When the sand pumping has been completed more water is poured in the hole, the tools run down again and the process of drilling repeated. In order to obtain an accurate prospect it is essential that the hole be cased with iron pipe and that the pipe at all times be kept within a foot at most of the bottom of the hole. When the prospect is completed this pipe is withdrawn by means of hydraulic jacks and can be used again.

If the pipe is not made to closely follow the drill a cave in is likely to occur in which case the prospect will, of course, be valueless; indeed if the cave is not discovered a very wrong estimate of the value of the ground may be arrived at as the actual amount of material raised will be much larger than the amount figured on, which latter is estimated from the size of the hole drilled. In order to obtain the best results in drilling it is necessary to make from sixty to sixty-five strokes per minute which can be done with the machine I am operating. The advantage of this, besides making the hole straighter and more rapidly, is that the cuttings as taken up by the sand pump are coarse and chunky and not ground to a powder as is the case when a slow short stroke is used. The long quick stroke keeps the heaviest materials afloat and does not allow them to settle between strokes to be recut or driven into the solid ground at the bottom of the hole at each descent of the drill bit and thus placed possibly out of reach of the sand pump. In order to make doubly sure of obtaining an absolutely accurate prospect a tool has been devised whereby it is possible, when prospecting ground having a soft bedrock, to cut into and bring up in a solid chunk about 4 inches of the bedrock, thus insuring the obtaining of every trace of gold, if any, which may have been driven by the driller into this soft bedrock. The cost per foot of drilling, whether there is water present or not, is a comparative constant and is in no case more than 25% of the cost of sinking shafts. For the purpose of prospecting thoroughly for dredging purposes, say a 100-acre tract to a depth of 50 feet, it is necessary to drill not less than ten holes spread over the tract. The cost of prospecting such a tract of land by sinking shafts might vary according to formation and conditions from $1500 to $20,000 and in some cases it could not be done at all. This reduction in the cost of prospecting will I believe, tend to greatly increase gold dredging operations in this State and elsewhere.

(On Golden Gate mountain, five miles west of San Andreas, Cal., F. J. Horswill of Valley Spring, Cal., used a driller of somewhat similar construction in locating an ancient river channel, boring several hundred feet through the lava cap which overlaid the gravel. He also recommends drillers highly for this purpose and for prospecting gravels generally.—ED.)

THE rain-making crank is again in evidence in various parts of the country. One in Montana proposes to deluge the earth by means of electricity; another in Los Angeles, Cal., proposes a general bombardment of the heavens from balloons sent up from Mt. Lowe. The first essential in rain-making is to supply the atmosphere with moisture sufficient to produce the desired precepitation, and if noise will bring about this desired humidity it would be a good plan to let the Los Angeles man try his experiment at his own expense, as suggested by himself.

BUILDING the Sierra railway into Tuolumne county, Cal., will prove of benefit to the mining industry in that section, if the result in other regions be any criterion. There are those who look upon the coming of a railroad into a mining region with alarm; but while it may for a time prove detrimental to a certain class—chiefly farmers—it will be found a great help to the general advancement and development of the mining section through which it passes. There are mines in that section carrying high-grade ores, and with better transportation facilities some of them should be directly benefited. The railroad will be a great convenience to the mining community.

GREAT importance attaches, in the minds of many, to the question, "Does the vein go down?" Admitting that it is desirable to have the vein, shoot, or whatever form of deposit it may be, "go down"—which condition is presumed to indicate permanency—is it so vastly important as to make a mine which does not go down valueless? Take two ore deposits of wholly different character, and compare them; for example, some of the mines in the vicinity of Terry in the Black Hills of South Dakota, where many of the ore deposits occur as flat or nearly flat sheets, extending across the top of a ridge, reaching from canyon to canyon. Some of these lie very close to the surface and require little stripping; others are not stripped, but mined and timbered. The ore deposit may be assumed, for convenience, to be 800 feet long, 130 feet wide and 10 feet thick. This represents a tonnage of 80,000 tons of ore, worth net, say, $15 per ton. This will place the net value of that particular mine or shoot at $1,200,000. After sufficient development has been done the owners may arrive quite arbitrarily at the net value of their mine. Yet this mine does not go down—no one looks for it to do so. There is no trouble with water, the mine can be worked systematically and economically. The mines in the district are not all as favorably situated as might be inferred from the example, but a type has been taken which represents the most superficial deposit—a cap on top of a ridge. In comparison with this take a fissure vein in California, standing at say 70°, which does go down. When opened to a depth of 800 feet and blocked out at a cost of not less than $65,000, it is found that the ore shoot is 300 feet long and averages 6½ feet in width and is worth $15 per ton. This represents 120,000 tons of ore, which must be extracted and hoisted at an expense of nearly a quarter of a million dollars. The pumps must be kept in motion without cessation. Everything in such a case is done at a disadvantage. The net result when the mine is worked out to the 800 level will probably be $1,400,000, and the mine may continue a large and profitable producer for many years more. But does the comparison make the flat shoot of ore capping the hill of so little value as not to be worth locating?

SECRETARY BENJAMIN of the California State Miners' Association has been officially informed by Secretary Raymond of the American Institute of Mining Engineers that that body will hold its next meeting in October, 1899, in San Francisco, in acceptance of the Association's recent invitation. The membership of the A. I. M. E. is about 2400, a percentage of which attends the stated meetings. It is probable that the San Francisco meeting will be the occasion of a large gathering of this representative mining organization. It will be the first time that the association will have met so far west, and the San Francisco gathering of this eminent body can be made the occasion of mutual pleasure and profit. There will be much for the visitors to see, and opportunity will be given to dispense California hospitality. Numerous details will have to be arranged for the proper reception and entertainment of the visitors, and it readily occurs to every one interested in the mining industry of this west half of America that it is to its advantage in every way that the sojourn of the A. I. M. E. be made as pleasant as possible. The meeting will be an event of importance to mining men on the Pacific coast, being the first meeting ever held west of the Rocky mountains by the Institute. The American Institute of Mining Engineers has been in existence twenty-nine years. The objects of the Institute are to promote the arts and sciences connected with the economical production of the useful minerals and metals and the welfare of all employed in those industries, by means of meetings for social intercourse and the reading of professional papers, and to circulate and publish among its members and associates the information thus obtained. The Institute consists of members, honorary members and associates. The members and honorary members are professional mining engineers, geologists, metallurgists, chemists or persons actively engaged in mining, metallurgy or metallurgical engineering. Associates include all suitable persons who, being desirous of connection with the Institute, are elected in accordance with the rules. The membership includes many men of greatest attainment, broadest knowledge and widest practical experience in the mining and metallurgical field, and the "Transactions" have taken a high place among the technical literature of the broad field which the scope of the Institute covers. Members from every corner of the globe contribute something of their personal experience for the benefit of those who are unable to visit the far distant section. The discussion which frequently follows original contributions forms one of the most valuable features of the "Transactions." In these mistakes or omissions by the original contributor of some paper are pointed out, or his ideas may be verified by the experience of others and amplified.

AS PROBABLY with every other publication, numerous inquiries are now received in effect: "When does the 20th century begin?" At 12 o'clock, midnight, Dec. 31, 1900. That is the brief correct answer. But the question brings up some additional reflections. There really is no 20th or 19th or any numbered century. The whole thing is arbitrary. By universal consent of Christendom a certain or uncertain starting point to count from has been selected; and, taking that as a basis on the 31st of December, of next year, 1900 years will have elapsed, and, as it takes 100 years to make what we call a "century," not till the last second of the hundredth year is a century completed. As with the first second of the year 1 began the first century, so with the first second of 1901 begins the hundred years that ends with the last second of the year 2000, called the 20th century. History has been defined as "fable agreed upon;" so with chronology. There is no reason for calling this the 19th century any more than the 29th or the 4th beyond the general acceptance of the idea that we must have some starting point, some way of numbering the years for convenience and the world's requirements. It would be interesting to know, were such a thing possible, what this year's number really is. Doubtless several times since the primal protoplasm evolved into the mammal, attempts have been made to keep correct record of the years. Doubtless those records were carefully kept, each succeeding 365¼ days being numbered one more with its predecessor till a large total accrued, and then, when the poor little human record of the years had aggregated 15,000 or 50,000, came a great cataclysm, its cause and result long since in oblivion, and the record began anew till another total of 15,000 or 50,000 years was attained, when another human convulsion compelled beginning the count anew. The insignificant little figures 1899 bear about the same relation to the real year of the world that an arc light does to the sun. It would be interesting, were it feasible, to know what the correct current date, from that standpoint, is—and about as profitable as to know when the 20th century begins.

PROSPECTORS who object to recording a claim with the county recorder, instead of with a local district recorder, as formerly, may note that the claim being recorded at the county seat, in the official books of the county, gives greater security to the title than when simply recorded with a district recorder, whose records were often poorly kept and frequently not kept at all. A copy of the certificate of location may be sent by mail, as it does not require the locator to appear in person at the office of the county recorder. The ambiguous language of location certificates is a fruitful source of trouble, as is also neglect to refer the corners to natural objects, such as large boulders, section corners, streams, etc. Trees are usually selected, and described by name and size, as "a pine tree 10 inches in diameter." The pine tree will grow with years, or may be cut or burned down, and then the bearing is destroyed. The location of a claim is simple and rarely requires the services of a surveyor to get the lines fairly accurate. Good, substantial monuments of stone, with a post not less than 4 inches in diameter, constitute legal and enduring monuments. If a locator considers his claim of any value, actual or prospective, it is surely entitled to have the corners defined in a positive and substantial manner, and to be recorded with the county recorder. If an opportunity to sell presents itself the owner has clear title, and in event of a transfer the deed must be recorded with the county recorder. Then, why not the certificate of location?

ON page 236 of this issue is a communication from "Mine Owner." The sentiment is concurred in. It might be further said lack of funds in the treasury of a mining company is not always responsible for parsimonious management nor for the many foolish things which are done at the mine. The superintendent is always held responsible for any evident mistakes in the development or equipment of a mine, but very often he has no voice in the matter. It is the board of directors who have the say, and sometimes they say very strange things. This is particularly the case with new corporate companies. The members of the directory feel the weight of their new responsibilities, and, while they may know little regarding the development of a mine or its proper equipment, they think they do, and want everyone else to think so, and the superintendent gets his orders forthwith: "Don't strike any more water if you can help it;" "keep away from soft ground—it requires timbering;" "the shaft is too big, reduce it to a single compartment," and so on. The superintendent usually has one alternative—to quit—for the directors do not propose to relinquish their prerogative and will not be instructed. The best way is for the board to engage the services of a competent superintendent, in whom they have confidence, and then give him full swing, for he, with the knowledge of the property, should, and certainly does, know better what should be done than the directors.

Concentrates.

A GRAIN of $18 gold is worth 3¾ cents.

QUARTZ containing 1 cent in one pound is worth $20 per ton.

IN placer mining 20 inches of water is usually considered a sluice head.

AT ordinary temperature a cubic foot of water weighs 62¼ pounds avoirdupois.

AMALGAMATION should be accomplished in a battery with the least possible amount of water.

THE average loss of quicksilver in free-milling ores should not exceed one-sixth ounce per ton of ore crushed.

COLORADO has passed an eight-hour-shift law for the benefit of miners, exactly similar to that in force Utah.

A MILLIMETER is nearly one twenty-fifth of an inch. A cubic centimeter is a very small fraction over .061 cubic inches.

AN assay ton contains 480 grains, being a troy ounce, and there are 29,166 troy ounces in an avoirdupois ton of 2000 pounds.

A CUBIC FOOT of quartz weighs nearly twice as much as a cubic foot of quartz sand owing to the interstitial spaces in the latter.

THE dredge that is to be operated in Stanley Basin, Idaho, on Marshall's and Cooper's placer ground, weighs about 225,000 pounds.

IN a 5-stamp battery the succession 1, 3, 5, 2, 4 is a good order of drop, and in a 10-stamp battery 1, 6, 3, 8, 5, 10, 2, 7, 4, 9 usually gives satisfaction.

THE square-set system of timbering was first introduced in the Ophir mine, Comstock lode, Virginia City, Nevada, in 1860, by Ph. Deidesheimer.

THE weight of freshly fallen snow varies from five to twelve pounds per cubic foot, depending on the humidity of the atmosphere through which it falls.

THE Catalpa Mining Co., Leadville, Colo., is shipping steel iron ore and fluxing iron to South Chicago. The mine is showing reserves of manganese.

AN exchange reports snow at Lane Mountain mines, near Elko, Nev., to be 10 to 18 feet deep. The miners pass from house to house through tunnels in the snow.

WHEN one sees the statement that "Mr. ———, mining expert, stakes his reputation on his report" on a certain district or mine, does it signify anything of importance?

A COPPER-SILVER MINE near Reno, Nevada, has the odd name of Cuag, being a combination of the chemical symbols for the two metals which it produces—Cu. (copper), Ag. (silver).

A No. 5 SCREEN has 20 meshes to the inch; No. 6, 25 meshes; No. 7, 30 meshes; No. 8, 35 meshes; No. 9, 40 meshes; No. 10, 50 meshes; No. 11, 55 meshes; No. 12, 60 meshes.

THE Nevada and Placer Co., Cal., miners employed by Mgr. Anderson to work for the Twin Springs Placer Co., Boise, Idaho, get $4 per day for pipemen and $2.75 for laborers.

THE recent Eastern advance in the price of steam boilers of 20% is occasioned by the rapid and continued increase in the price of materials entering into boiler construction.

A SHAFT having an inclination of 60° from the horizon, departs from the perpendicular 50 feet in each 100. One at 45° gains 70.7 feet in each 100 and one at 30°, 86.6 feet in each 100.

FROM the Golden Gate mill at Mercur, Utah, last week was received at Salt Lake City one consignment of auro-cyanides, weighing 6000 pounds, and calculated to be worth $20 per pound.

MARCH is a bad month for snowslides in Colorado, and the unusually heavy February snowfall threatens a continuance of the present timber famine in the higher altitudes of that commonwealth.

WATER flowing from the shafts or tunnels of many copper mines contains sulphate of copper in solution. By passing this water through a sluice box or tank containing old scrap iron metallic copper is deposited.

A QUESTION of some importance in California is: how may the large piles of roasted sulphides (tailings of chlorination works), containing values in gold of $5 per ton and upwards, be successfully treated at a profit?

A MIXTURE of absolute alcohol and ether, in the same proportions as are used in making collodion, is a solvent for celluloid, and will not interfere with any of the coloring matters used in the preparation of the article.

AT Hedges, California, 120,000 gallons of water were pumped from the Colorado river to an elevation of 500 feet at the mines, a distance of twelve miles, at a cost of $22 per day, or about 22 cents per ton of ore treated.

THERE was a stampede to the Buffalo Hump district in western Idaho in '62, caused by the report of rich placers, but none of value being found the stampeders left the field. No attention was given to the quartz veins at that time.

THE careful sizing of pulp from batteries before sending it onto concentrating machines gives better results. It is scarcely reasonable to expect to save coarse and fine sulphurets on a single belt or table with an equal volume of water and the same grade.

AT the Redman mine, Banner, San Diego Co., Cal., 12 inches of water were raised from the shaft from a depth of 90 feet by means of a hydraulic ejector. To accomplish this, 9 of the 12 inches were introduced under a 650-foot head, through a 4-inch pipe.

TO FIND the approximate weight of a conical pile of quartz, measure the diameter of the base in feet, square this diameter and multiply by .7854. This will give the area. Multiply this sum by one-third the vertical height of the cone-shaped pile and divide by 20. This will give the number of tons in the pile. Example: A pile of ore is 12 feet wide and 4 feet high, piled in circular form; 12 12 144. This multiplied by .7854 equals 113.09 1', feet (one-third the height) 150.4 cubic feet. This divided by 20 (the number of feet in one ton) gives 7.52 tons.

NEAR Prescott, Arizona, search is being made for rubies by a man who claims to have noticed them there years ago, at which time he did not recognize their value. Should he find the place again, his rubies will in all probability prove to be garnets of no great value.

IN some Southern States chlorination can be successfully accomplished at a cost of but $5 per ton of concentrates, owing to low cost of labor, fuel and chemicals. In California the cost ranges from $6 to nearly $12, according to magnitude of operations and conditions.

THE relative height of discharge from a stamp battery influences the capacity. A low discharge increases capacity, a high discharge retards it. While increased capacity may result in cheapening the cost of crushing per ton, a loss of gold from more rapid crushing may result in a loss instead of a gain.

A MINER'S inch in California is a variable quantity, ranging from 1.36 cubic feet to 1.73 cubic feet per minute, according to height of pressure. When the surface of the water is exactly 6 inches above the center of the discharge (2 inches in height) each square inch discharges 1⅓ cubic feet per minute, or 12.09 gallons.

A PROJECT is being agitated to run a large drain and transportation tunnel from Malta, Colo., in the valley of the Arkansas river, under the mines of Leadville. The tunnel would be several miles in length, but the conditions obtaining at Leadville warrant the undertaking. The miners are asking State aid to accomplish the great task.

WERE the Standard Electric Co. of California to complete its project of bringing electric energy from Blue Lakes to Oakland, Cal., the transmission wire would be the longest in existence—125 miles. The project is deemed feasible. In southern California high voltage is now carried eighty miles, a distance that a few years ago was considered impossible.

THERE is no business quite so legitimate as mining, rightly says Judge Goodwin. In other occupations when men obtain money they have to go down into the pockets of other men to get it. They may give full value for it, but after all it is only a "swap." When they take it from the ground it is a creation, and blesses not only him who receives it, but all the world.

THE French metre is 39.370432 inches and is presumed to represent the one ten-millionth part of the distance from either pole to the equator, but after having been adopted errors were found to have been made in the calculation, and in consequence is not what it was intended to be, but approximates it closely. Taking it at 3 feet 3⅜ inches, the length of the metre is but 1 part in 8616 too great.

A WASHOE COUNTY, Nevada, legislator has introduced a bill in the Assembly to restore the provisions of the original mining tax measure, providing that in no case shall the exemption from taxation of any mine exceed 90% of the proceeds of ore that yields $12 or less per ton; 70% of the gross proceeds of ore that yields over $12 and under $30; 50% on ore from $30 to $100; and 35% on ores over $100.

IN an article on the chemistry of coke in *Revue Universelle*, O. Simmersbach of the Westphalia Coke Syndicate sums up the following points which should be insisted on in a good coke for metallurgical purposes: (1) Not over 4% of water; (2) not over 9% of ash; (3) not over 1% of sulphur; (4) not over 0.18% of phosphorus; (5) not over 6% of fine coke in any shipment; (6) a crushing strength of at least 1140 pounds per square inch.

RAPIDLY fluctuating values in mine stocks have a tendency to influence capital against mining as a legitimate industry. The price of mining stocks at the exchanges seldom bears any actual relation to the real value of the mine as determined by "ore in sight." When a mine is prosperous, its stock is usually selling at a price above its actual value; and when not paying stock is often below its reasonably safe prospective value.

"WHEN a broker creates a market," says one of that fraternity to the Salt Lake, Utah, *Tribune*, "he has a right to fill his order at the figure to which the seller has responded, without interruption from any other buyers, and the sooner that principle is recognized and incorporated in a rule, the better for brokers. The only fair means of side-tracking the original buyer is to make a better market. Observe this rule and the daily conflicts will have been overcome."

WHEN the Utah Consolidated, Utah, mine was a gold mine it sold at $1 80 per share. Now that it is a copper mine it has sold at $30, which for the 300,000 shares would make it worth $9,000,000. Last week a company represented by H. H. Rogers bought 100,000 of the 300,000 shares for $3,100,000. Boston men who parted with the stock paid $5 and $6 per share for it about two years ago. The stock is understood to be selling at $30 per share at present.

ACCORDING to a recent patent, iron or steel can be colored by cleaning and dipping in a solution of the salts of one or more metals. It is then placed successively in a dry chamber at 100° Fahr., steam, the dry chamber again, and boiling water, for about thirty minutes in each, and then scratch brushed. The solution used can be made by mixing hydrochloric and nitric acids with perchloride of iron and some sulphate of copper and water. Metallic iron is added and the solution is filtered. Coloring matters may also be added.

THE fulminates of the various metals—gold, silver, mercury, etc.—are preparations of these metals which have the property of exploding or detonating, more or less violently, under certain circumstances, such as being struck a sharp blow, being scratched and even on being touched. Some explode even when the surrounding atmosphere is put into certain forms of vibration, vibrations of a certain velocity, etc., as by the explosion of another substance. The term fulminate has no reference to the chemical make-up of the substance.

THE structural geology of Calico district, Cal., is not unlike that of Cripple Creek, Colo. A heavy deposit of rhyolite-breccia and tuff lies upon an older system of crystalline rocks in the Calico region. The breccia and tuff are cut by intrusive dykes of t.parite and vitrophyre. The ores, however, occur in fissures, chiefly in the breccia. Hornblende andesite forms a large portion of the southeastern hills at Calico. At Cripple Creek andesite lies in heavy layers upon the granite. The andesites are cut with intrusive dykes of phonolite. The ore shoots in Cripple Creek are usually associated with these dykes.

THE first time electricity was used in mining in California was in Placer Co. in '89. The first use of the kind in Colorado was by the Aspen M. & S. Co. at Aspen, where, in the Veteran tunnel, a street car motor was rigged up to haul a train of empty cars 1200 feet and to raise from an incline. A vertical shaft to tap the Molly Gibson vein was sunk and operated at a depth of 1230 feet with the largest electric hoist in the State. In Cripple Creek there are fifty electric hoists in operation, using the induction motor, varying from 5 to 50 H. P. There are now two under construction of 200 H. P. each and one of 300 H. P.

BY specific gravity is meant the weight of a body as compared with the weight of some other body of equal bulk which has been adopted as a standard of comparison. Pure water is the usual standard excepting for air and gasses generally. Where extreme accuracy is not essential no account is taken of temperature of the water nor atmospheric pressure. The manner of ascertaining the specific gravity of any body heavier than water is as follows: Weigh the body in air, then in water; find the difference, which represents what the body loses in water, and is the weight of a bulk of water equal to the bulk of the body immersed in it. Then by proportion—as the difference is to the weight in air, so is one to the specific gravity of the body.

THE "smokeless giant powder" recently reported invented is the product of A. Moffatt of Indianapolis, Ind. So far as the writer knows, it has not as yet received any practical test. In Sydney, Australia, Messrs. Fraser & Callaghan have invented a smokeless blasting powder that they call "kallenite." The base is "eucalyptus leaves and titree bark," instead of infusorial earth. An account of a recent test at Sydney of "kallenite" says: "Four holes had been drilled to a depth of 16 feet, and each had been charged with twelve pounds of 'kallenite.' The charge was fired by electricity, and dislodged with comparatively little upheaval some 200 yards of stone. There was little noise and hardly any perceptible smoke or fumes."

AIR in passing through pipes is subject to friction in the same manner as water or any other fluid. Frictional resistances in pipes conveying fluid are proportional to the density of the fluid. At equal velocities the frictional resistance of air is very much less than that of water. Air may be transmitted in mains, without serious loss or fall of pressure, at ten to twenty times the velocity practicable with water in water mains. Air at ninety pounds is 115 times lighter than water, and frictional resistance at equal velocities is less than 1% of that of water. In air mains velocities of 25 to 50 feet per second are allowed without serious frictional loss. In consequence of this high velocity large amounts of power can be transmitted by air at moderate pressures in pipes of moderate dimensions. It is seldom necessary to use anything above 6 inches in diameter; 5 inches has been the size of pipe most utilized, and as low as 2 and 3 inches. In pipe lines of a mile or over the difference in pressure at both ends is hardly appreciable.

FLASHLIGHT powder usually consists of either magnesium, in powder alone, or with the addition of an equal weight of aluminum in powder and 20% of potassium chlorate. Another formula consists of 15 parts (by weight) of gun cotton and from 15 to 30 parts of magnesium in powder. They are to be "mixed" as follows: Pull out 10 or 15 grains of the cotton in such a way that it makes a thin, round layer from 3 to 4 inches in diameter. Sprinkle over it, evenly, a similar amount of powdered magnesium (which you can purchase already powdered); lay over it a layer of the cotton similar to the one first prepared, and the light is ready for ignition. The operations described before should be performed on a dust pan or similar object (a sheet of tin will answer); and, after putting on the covering layer as described, attach a fuse, 6 inches or more in length, according to the time desired, made of twisted cotton that has previously been dipped in a solution of potassium chlorate, or a mixture of chlorate and nitrate, and dried. Taking flashlight photos in mines requires the proper apparatus and a natural aptitude therefor. The sample sent is not suitable for engraving; too dark. The utmost care should be used in the manipulation or manufacture of flashlight powder, as carelessness is apt to result disastrously.

RECENT advance has been made in the treatment of zinc ore containing iron by magnetic separation. The separation of the two metals had hitherto only been possible in cases where the particles were of comparatively large size so as to allow of their treatment by a process of concentration by gravity, the iron being the heavier. The impurities which affect the value of the zinc are iron and lead. The former, which is the most frequent, renders the metal much harder and causes it to heat and crack during the rolling of zinc plates. Lead is generally present to a small degree, being introduced from the galena which so often accompanies the ore. Zinc is extracted by a process of distillation, which is rendered easy, as the metal volatilizes at a bright red heat. When the sulphide is used for this purpose it is first roasted to get rid of the sulphur. Lead is separated from the zinc during the treatment by heating the pigs of zinc on the sloping bed of a furnace. As they melt and run down to the bottom the lead, being the heavier, collects in the bottom of the hollow and the upper layer of zinc can be run off. The deposits in which the ore is usually found are, like most deposits in limestone, irregular fissures and pockets connected by stringers. The ores which occur are the sulphide of zinc (blende) and the carbonate (calamine). The former carries 60% zinc when pure, but averages 40% to 60% in practice. Calamine is a white, pearly ore containing up to 52% zinc, and was for a long time the principal ore worked. The red oxide of zinc is found in some places. When heated before the blowpipe it gives a characteristic incrustation on the charcoal which turns green when moistened with cobalt solution and reheated. Various other metals in combination prejudice this test. Galena has a specific gravity of 7.5, blende 4.3 only, so that the one ore is nearly twice as heavy as the other. Galena is also much softer than blende.

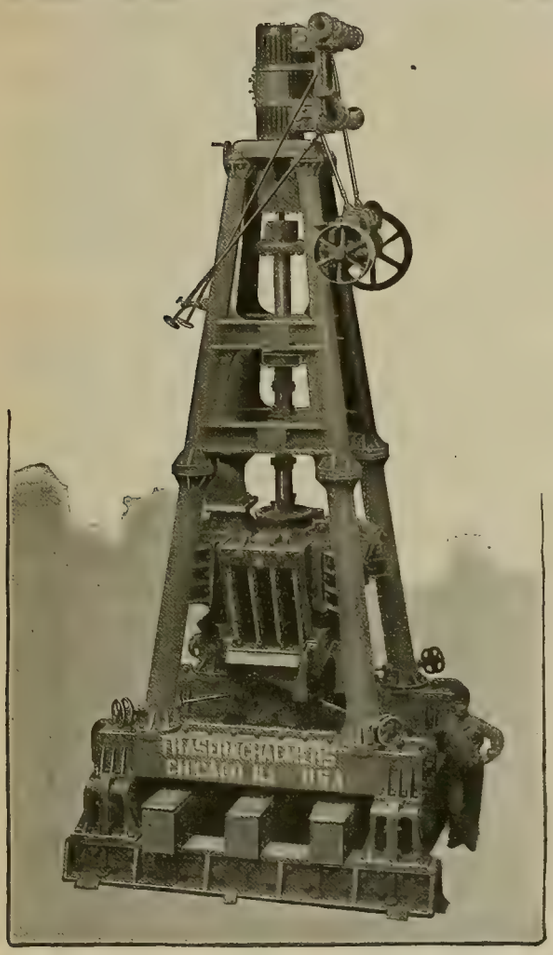
Notes on Steam and Other Stamps.

Written for the MINING AND SCIENTIFIC PRESS by C. H. FITCH.

A valuable summary of information on the steam stamp is contained in the historical paper by Frederick G. Coggin, superintendent of the Calumet & Hecla mills, Lake Linden, Michigan, before the American Society of Mechanical Engineers. Messrs. Blandy, Rolker and Munroe have presented interesting papers on the subject before the American Institute of Mining Engineers. An official report (1898) by Geo. A. Newett, Commissioner of Mineral Statistics for the State of Michigan, gives additional facts.

From these and other sources I gather the following memoranda, not as being exhaustive in treatment or infallible in opinion but rather as foot-marks along the line of progress in steam stamps, leaving much to be said:

The first steam stamps were built from the designs of William Ball of Chicopee, Mass., in 1856, for a mine in South Carolina. These had cylinders 9 inches in diameter, 24 inches stroke, stamp stem 6 inches in diameter. A slide valve was used with an eccentric driven by a train of elliptical gears. These gave a wide admission of steam for the down stroke, but only a small opening, about $\frac{3}{16}$ inch, for the up stroke. The mortar was shaped in section very much like a bottle, with a single screen opening about one-quarter way around it.



STEAM STAMP FOR THE ANACONDA COMPANY, BUTTE, MONTANA.

The usual steam pressure was eighty pounds per square inch; blows per minute, seventy five; capacity about fifty tons of rock in twenty-four hours. Stamp frame and sills were of wood. Weight of anvil under mortar was about eight tons; of reciprocating parts, 2000 pounds, including shoe 15 inches long, 12 inches wide, 6 inches thick, and weighing about 300 pounds. Steam was wastefully used with great compression at the upper end of the stroke, and great clearance at both ends.

A later type of Ball stamp was placed on the Franklin mine in 1861, remodeled in 1865, and recently supplied with solid anvil blocks. These stamps are in commission after thirty eight years of service, three of them pounding out 450 tons a day. The 1865 design had 12 inch cylinder, 8 inch stamp stem, shoe weighing 500 pounds and anvil about ten tons. The screens were placed on two sides, aggregating four times the previous area, and were higher relative to face of die (apparently about 20 inches, scaled from a small drawing). The mortars were also lined, and were of the modern flaring type, angle of inclination being increased from 10° to 30° from the vertical. Iron sills took the place of wood, and spring timbers 14x18 inches were increased in number from three to seven for greater stiffness.

This change indicated that there was some appreciation of the fact that there was too much "give" to the spring timbers which spanned sills some 9 or 10 feet apart, but it was years later before they were displaced by solid anvils, a suggestion claimed by Edwin Reynolds some time after E. D. Leavitt Jr. had built the stamps of his design with pyramidal frame of iron columns for the Calumet & Hecla mill.

The Ball stamps at the Franklin mine, as first improved, had a capacity of 100 tons of rock in twenty-four hours, a gain of fifty tons, about thirty-eight of which was apparently due to larger cylinders and twelve tons to increased weight of stamp and timbers, and larger screens. But upon this improvement the solid anvil appears to have made a further gain of 50%, reaching a capacity of 150 tons.

The Leavitt stamps had practically two superposed single-action cylinders, the pistons fixed on one rod. The upper piston was first 20 inches (later design 21½ inches) diameter, and the valve gear was of the cam and yoke order. Between the pistons was a space in vacuo, and a uniform pressure for lifting the stamp was maintained under the lower piston which was smaller, 11$\frac{11}{16}$ inches and 14 inches in different models. The object of this was to reduce wasteful clearance which in some of the Ball stamps amounted to 50% of the space swept by the piston.

It was an idea of A. H. Emery to simplify all this by using one single-acting engine with no lower cylinder head, the stamp being lifted by atmospheric pressure. This he never worked out, and it is an example of a good and practicable idea left slumbering because no one is ready to take hold of it. It may be superfluous to mention that Mr. Emery was the designer of the system of testing machinery used at Watertown arsenal and elsewhere, ranking in my opinion, in point of originality of design and range of combined delicacy and power, as one of the seven wonders of modern mechanism. I say this because, popularly speaking, an ingenious mechanician is obscured by the forwardness of advertising engineers, and as showing that he had the ability to make good practice of his ideas on steam stamps if he had chosen.

To return to the Leavitt stamps: the mortar was four sided, doubling the screen area, and was made two tons heavier, the anvil weighing twelve tons. The clearance was reduced first from 50% to 22%, and then by a further decided improvement employing a dash pot with rubber cushion, it was found practicable to reduce it to 5$\frac{7}{10}$%. By these changes the saving of fuel over the old Ball stamp was first 10% and finally 40% and the increased capacity first 25% and then 50%, the steam pressure being ninety-five pounds per square inch. At this stage the capacity was 240 tons in twenty-four hours. Subsequently the steam pressure was raised to 107 pounds and a solid anvil displaced the spring timbers, the total weight of iron base and anvil being 120 tons instead of the smaller anvil (at first twelve and later twenty-three tons) on spring timbers. This brought the capacity up to 300 tons.

All these capacities relate to crushing through $\frac{5}{16}$-inch mesh screens, as has until recently been the common practice.

In 1880 some twenty-six Ball stamps were enumerated by Munroe as in use at Lake Superior mines, and in cases cited averaged per stamp about 144 tons on amygdaloid and 105 tons on conglomerate rock. A battery of seventy-two 1000-pound ordinary stamps is at the same time credited with about four tons per stamp.

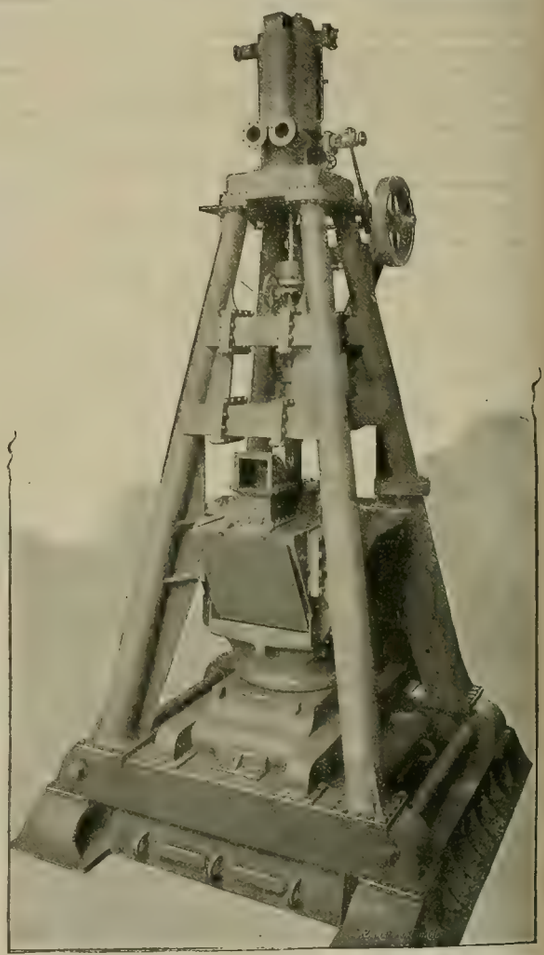
About 1883 and later improved Ball stamps with pyramidal columnar iron frames were built in considerable numbers by Fraser & Chalmers. One of these is shown in the illustration herewith, a man standing beside it giving an idea of the height of these machines, which is about 30 feet. No less than thirteen of these were built for the Anaconda Copper Mining Co. and used both on copper ores to be concentrated and on silver-bearing ores to be treated by pan amalgamation. They were also supplied to the Broken Hill Proprietary and other Australian companies; to W. A. Clark and to the Homestake mine, where one was used for a time on gold ores. This last I think was equipped with sectional screens patented in 1891 by T. J. Grier, superintendent of the Homestake. While increase in screen area makes some gain in capacity, it is by no means proportional with increased area. The lower part of the screens do most of the work and take most of the wear, from which the advantage of sectionalizing is obvious.

These improved Ball steam stamps were, so far as I know, the only machines of their class and size extensively used in fine crushing, having a capacity of 150 tons a day when so used.

On coarse crushing their capacity reached 230 tons even with the spring timbers then universally used. They gave ninety blows per minute. The largest of them having only 15x30 cylinders, it will be seen that their capacity compares favorably with the larger Leavitt stamps even after the latter were provided with solid anvils.

Some of their details are here noted: The anvil or bedplate was 20 inches thick, weighed eleven tons and was placed on a 1-inch thickness of rubber. The mortar was set in planed angle guides of the frame with gibbs adjustable by set screws and jam nuts. The guides were bronze bushings in cast-iron brackets. The slow turning of the stem was accomplished by means of a pulley sleeve on the stem, brass-bushed, and with two feathers fitting slots in the stamp stem. Ball first attempted to turn the stem with gears, but afterwards used a belt. One-inch Manila rope is now used.

The method of attaching shoe is by a dovetail tongue into stamp head. The method of attaching piston rod to stamp stem is by a circular disc on the rod, being encased in rubber within a bonnet secured to the flange of the stem. Both of these methods are approved by long satisfactory usage. The piston was of steel with bronze packing rings. The whole weight of machine, including spring timbers, was about 140,000 pounds.



FRASER & CHALMERS' STAMP FOR THE TAMARACK MINE, MICHIGAN.

Water was fed to the stamp through a circular ring about the stem. The volume of water required in the crushing and concentration of copper ore is very great. According to Rolker, in 1876, at the Allouez mill, with two stamps crushing about 200 tons of ore a day, 1556 gallons of water a minute were required for the whole mill, but of this only 200 gallons a minute were fed to the stamps. The Atlantic mill, with a capacity of 320 tons of ore a day, used 2200 gallons of water a minute.

The following are recent reports of steam stamp service: The capacity of Ball steam stamps at Lake Linden was 275 tons for 18x24-inch and 325 tons for 20x30-inch cylinder stamps crushing from 3 inches through $\frac{3}{8}$-inch screens.

Old style wood frame stamps at Atlantic mine: Cylinders, 20-inch; steam pressure, 105 pounds per square inch; blows per minute, 95; valves, double-slide, with auxiliary valve for regulating up-stroke; capacity with spring timbers, 200 tons, but some have been changed to solid foundations, and this, with perhaps other improvements, has given them a capacity of 316 tons and more.

Mr. C. H. Krause, superintendent of the Osceola mill, states the gain of solid anvil over spring timbers to be 35% to 40% in capacity. The new Osceola

steam stamps will have improved mortars with circular screens and shoes of new form, 15% heavier than previous designs. With other modern features and methods they are expected to pass the 500 ton mark.

In a report of the Tamarack Co. for 1897, by W. E Parnall, it is stated that there were seven 20 inch cylinder stamps in use. Their duty was equivalent to one stamp run 1915 days, crushing 640,000 tons of hard conglomerate, an average of about 333 tons in twenty four hours; cost of stamping, 28 cents a ton.

Having traced progress from the original Ball stamps, I reach the climax of my chapter in the new Tamarack stamps built by Fraser & Chalmers, one of which is shown in my second illustration. These have 20-inch cylinders. The maximum drop is 24 inches and the falling weight 6500 pounds. They have solid anvil base, quadruple discharge mortars, and a new valve gear, light, quick-acting and with small clearance. The valves are rotative, similar to the Corliss valve. They have shown the great capacity of over 500 tons in twenty-four hours.

A feature which contributes to this large capacity is the method of crushing through a coarser mortar screen, $\frac{5}{8}$ inch or $\frac{9}{16}$-inch instead of $\frac{3}{8}$-inch as formerly, the pulp being then passed through a revolving screen with $\frac{3}{16}$-inch or $\frac{1}{4}$-inch holes, and the oversize elevated and returned for recrushing.

At the Osceola mill, where a similar practice prevails, they have tried sending the over-size to a stamp with finer mesh screens, but have found this unnecessary.

The use of more solid foundations in ordinary stamp batteries also promises some gain in capacity. The new stamp mills of the Alaska Treadwell and allied companies were equipped by Fraser & Chalmers with 1130-pound stamps and solid anvil blocks on a concrete foundation. They have also supplied other mills with heavy cast-iron anvils under the mortars. The resulting capacity appears better than usual, but the conditions do not admit of positive comparison on this one point. The gain may be 30%, but perhaps not so much as the timber foundations of batteries are relatively more rigid than the spring timbers placed under steam stamps, so that there is not quite the same room for improvement.

Geological Features of Some Desert Mines.

Written for the MINING AND SCIENTIFIC PRESS.

The mines at Hedges and vicinity, in the Cargo Muchacho mountains, San Diego county, California, are not veins but bedded deposits without defined walls, the economic conditions determining where mining shall cease. The gold-bearing rock is highly silicious, but altered from its normal condition. Large reticulated granitic dikes intrude the gold-bearing formation, and for that matter the entire region, but these intrusions seem to have enriched the gold-bearing horizons, of which there are several. The ore is copper stained (malachite) and is made up of quartz, epidote, hornblende, chlorite, feldspars, and other minerals which occur less sparingly than those mentioned. All of these have been found gold-bearing except the epidote. The gold is usually quite fine, though visible gold not infrequently occurs in the upper levels. The pay ore can nearly always be distinguished from that which is worthless by its physical appearance and sometimes by the sense of touch. The former is bright and "lively" looking, while ordinarily the latter looks dull and grayish and has a harsh feel. The American Girl mine, situated more than a mile from the mines at Hedges, may be in the same geological horizon, but if so it is the result of a fault. If not, then this gold-bearing series has an immense thickness, as the mines at Hedges dip toward the American Girl. The Cargo Muchacho mountains are divided into two distinct masses by a canyon which cuts directly through the center of them, and the group of hills on the south is distinctly different from the group on the north. This difference may be observed plainly miles away. It is not improbable that the canyon marks a line of fault and that the American Girl mine, which is on the southerly side of the canyon, belongs to the same series of rocks as those at Hedges. The occurrence of the ore shoots and the mineralogical features in each group of mines are essentially identical.

Forecasts by Means of the Aneroid Barometer.

TO THE EDITOR:—I possess an aneroid barometer with thermometer attached. Would you kindly give me a means of telling the state of the weather by means of these?

TO THE EDITOR:—Replying to your correspondent's question regarding the best means of predicting the weather by the use of an aneroid barometer and thermometer, I must say that while he will find the instruments useful, still the character of the work that he will be able to do would be very crude indeed. Readings of the aneroid barometer are dependent upon elevation. It will be necessary for him to read his instrument frequently, keeping it in the same position, and in the course of a few months he will be able to determine about what is its normal condition. High stages of the barometer are favorable for fair weather and low stages for rain. A rapidly falling barometer is an indication that a severe storm is approaching, especially when the wind changes toward the southeast. The more rapid the barometer falls, and the lower the stage that it reaches, the more severe will be the storm; but the faster the barometer falls the shorter will be the duration of the storm. A slowly rising barometer is indicative of fair weather which is likely to continue for some time, while a rapidly rising barometer will cause quickly clearing weather which is not likely to last very long. W. H. HAMMON,

Professor Weather Bureau.

San Francisco, Cal., Feb. 23rd, '99.

Some Experiences of a Working Miner.

NUMBER IV.

Written for the MINING AND SCIENTIFIC PRESS.

In one of my trips to an out-of-the-way district I ran across a man who had located a fine-looking quartz vein. The rock looked well, some of it very well—good enough, the owner said, to eat. He had built a good arrastra and crushed a lot of rock, but got little gold. He reached the conclusion that the arrastra was not suited to the treatment of his ore, and, having money enough for experimental purposes, built a 5-stamp mill fitted with water power and all modern attachments. When complete he started up, but still the rock refused to give up enough gold to pay for milling to say nothing of other expenses. I asked him if he had ever had any of it assayed and he replied he didn't believe in it. I finally persuaded him to have some of his best ore tested which he reluctantly (it seemed to me) did, and it was found to contain about 60 cents per ton. He declared the assayer did not understand his business. It took considerable argument and the loss of several hundred dollars more in money to convince him his ore was valueless and now he has a good little mill for sale cheap.

Col. D—— was owner and superintendent of the S—— B—— mine at G——. He was always wide awake and did business with a rush. The contractors had scarcely turned the mill over to him before he had the whole plant in full blast. The ore contained a large percentage of lead, chiefly as sulphide. It would not amalgamate freely raw so a White & Howell rotary furnace had been put in. The ore passed through a dryer, was crushed dry and lifted by a bucket elevator and dumped in the hopper of the furnace. For a day or two things went along smoothly and then the trouble began. A mistake had been made in the construction of the furnace foundations—they were too close together. This would under ordinary circumstances, perhaps, have occasioned no serious difficulty, but with that high-grade lead ore the intensity of the heat of the furnace caused the pulverized ore to assume a semi-pasty condition and it fell dripping from the lower end of the furnace into the discharge chamber. After a time it had plastered the fire bricks of the wall opposite and then it was wound and twisted about like molasses taffy between the furnace and the wall as the furnace revolved, until finally it became evident something must be done. Probably a rough sorting of the ore to reduce the percentage of lead would have accomplished the desired result, but this was not thought of, or if it was the idea was rejected. The elevator was stopped and the fire allowed to burn out and the furnace to cool in order to make the necessary change, but the stamps were not hung up for a moment. For nearly three days the dry pulp continued to discharge from the batteries, and, as there was no other place to put it, it was spread out on the floor a mass of heavy yellow dust a foot deep. Meanwhile the cylinder of the furnace was moved upward into the foundation at the feed end. When the change had been made and the fires gotten in full blast again the mill foreman, tired out with the hard work, went home to rest and sleep and I went with him, the colonel himself assuming charge. Before we left the ore elevator had again been started and everything seemed to be running smoothly. After supper we both retired for the much needed rest. About 10 o'clock that night a loud knocking at the door aroused us. The foreman asked what was wanted. A voice replied "the colonel wants you both to come to the mill at once, the d—l is to pay down there. The mill has been on fire two or three times already." We hastened to the mill and there saw the colonel in his shirt sleeves with the fire hose in hand trying to prevent the complete destruction of the mill. The entire floor space in front of the discharge chamber of the furnace was filled with red-hot pulp, the doors were open and a perfect cataract of molten fire was pouring from the chamber. The doors could not be closed and it looked serious indeed. The large amount of pulp coming from the furnace surprised us and we could not understand it, but going around for the purpose of stopping the elevator we discovered dimly through the darkness, dust and smoke at least a dozen men formed in a line armed with buckets. These men were dipping up the pulp in front of the batteries and passing it along from hand to hand, it was being poured into the hopper of the furnace at an astonishing rate in addition to that lifted by the bucket elevator. The foreman signaled them to quit at once and stopped the elevator also. The colonel, who had followed us, when he saw what had been done danced excitedly about and motioned us outside. We followed, and as soon as we were out of the door he bawled in our ears, "I want to get through all I can—I want to clean up the mill." "All right," replied the foreman, "you run it and I'll go home." "No," said the colonel, "you fellows run it, I am going home."

The danger of fire being over, the colonel told us at a little distance from the mill that, after we had gone home, it had occurred to him that he might as well run through the pulp lying on the floor, and conceiving the idea of the bucket brigade had sent up town and hired a dozen idle men and set them at work. For a time all went well. The first charge was cleared away from the furnace and sent to the pans, but the second charge quickly accumulated. This was not wholly removed when the doors of the furnace were bursting open with the third charge. It went from bad to worse and at last he could not get near enough, owing to the red-hot pulp on the floor, to shut the doors, but it had never occurred to him to shut off the supply.

After the colonel had gone home we hung up the stamps and in time removed the pulp, but it was not properly chloridized nor oxidized and all that had not been charged in the pans had to be sent through the battery a second time and reroasted. It took all of three days to clean up the mill and get things working systematically again.

It is said "haste makes waste." It certainly did in this instance.

The U. S. mine was discovered by poor prospectors, who, by following a small rich pay streak in a very wide vein, took out enough gold in a mortar by hand to pay for a 1-stamp mill. With this little mill they made enough money to buy a second-hand 15-stamp mill, of which they managed to keep five stamps working, and took out a moderate fortune and then sold out to a company. The manager of the big concern evidently thought the mine rather a small affair and immediately ordered a 60 stamp mill and built a big hoisting works. When completed the entire vein was stoped 50 to 100 feet wide, but it never paid a dividend. The little pay streak was there, and that worked separately was a good little mine in itself, but the great barren ledge in which it occurred with little or no value aside from the small streak resulted in failure. This is a lesson which teaches us that rock too poor to pay for milling is not made profitable by mixing with ore that is rich. This is a popular fallacy among many miners. MINER.

A Handy Power Hammer.

Herewith is a sketch of a foot hammer used satisfactorily by different smiths. J. D. Hall, Orrville,

O., the inventor, says: "It will do almost any kind of work. I weld, swage and cut iron from $\frac{1}{4}$ inch and can weld steel toes to horseshoes (sharpened) in three blows. I can do the work of two men with this hammer, and it is just the thing where a man needs a helper, but cannot always have one. I might add that the power can be attached by the taking off of the springs."

ROPES of all sizes can be automatically measured by a new machine, which has a roller journaled in a casing around which the ropes are passed and then extended through openings of different size to correspond with the diameter of the rope, the roller turning pointers on a dial as it revolves.

Analogy of the Ore Deposits of the Black Hills and Leadville.

Written for the MINING AND SCIENTIFIC PRESS.

In the Black Hills of South Dakota, in the Cambrian rocks of the northern hills, have been developed mineral deposits of great interest and value. These deposits occur in the formations lying near the base of the sedimentary series including the Cambrian (principally quartzites, sandstones, impure limestones and calcareous shales) and Carboniferous limestones, some of which are magnesian. A marked feature of the sandstones of the Cambrian is the occurrence of glauconite (a hydrous silicate of iron and potassium of pale green color). In only one instance is this sandstone metal-bearing in the knowledge of the writer, that being found on the east side of Spruce gulch, a mile and a half east of Deadwood, at which place is found a deposit of silver-lead ore, associated with an eruptive dyke. The ores of the Cambrian occur at several different horizons, being in some places silver-bearing, usually with lead, and in others the value is chiefly in gold in the form of telluride. The character of these ore deposits varies in different districts, though in the same geological horizon. In Ruby basin and vicinity the lower quartzite member contains chiefly gold; in Spruce gulch the same horizon develops silver-lead ore, and the same is the case near Green mountain. Near Garden City both gold ores and silver-lead ores are found. Immediately overlying this basal quartzite, in highly silicious (altered) shales, rich telluride ores are found in several localities. The upper quartzite horizon, lying about 200 feet higher (this bears no relation to altitude), is the repository of valuable ore bodies also, in it occurring both gold and silver-lead ores at numerous places, and always at contact or near an eruptive dyke. Gold also occurs, sometimes native, in silicious masses (chert) in the limestones of the Carboniferous. The lower member of the limestone, a buff calcareous shaly rock, may possibly be Devonian, but this is not important from an economic standpoint.

In the massive gray limestone of the Carboniferous have been found, at several localities, bodies of lead-silver ore of value, notably those of West Virginia City (Carbonate Camp). Similar ores occur near Deer mountain, five miles south of Lead City, and near Galena. In every instance these ore shoots throughout the Cambrian and Carboniferous formations, whether in quartzite, sandstone or limestone, are associated with intrusive dyke rocks which, ejected from below, have cut through all the sedimentary formations, and where favorable exposure by erosion has taken place these dykes may be seen in the underlying Archæan schists, proving that they were ejected from great depth, and doubtless have formed the channels through which these ore deposits have derived their values.

The eruptive rocks of the northern Black Hills are all of the Pretertiary series, including rhyolite, trachite, phonolite and some rocks more closely allied to the andesites. These rocks occur in two distinctly characteristic forms. First, great masses forming mountain peaks, as Terry, Black Butte, Custer and Sugar Loaf, and many of lesser magnitude, which have injected vast sheets from the uncleal mass into the sedimentary beds of the region, lifting them sometimes from their contact with the upturned Archæan and in many places splitting the Cambrian and Carboniferous rocks at various horizons. Some of the quartzite beds have sheets of rhyolite both above and below, being isolated over large areas from all contact with other Cambrian rocks.

These sheets of rock, which are usually rhyolite or trachite, become thinner with increasing distance from the main mass of which they form a part. This is that type of structure known as the laccolite and is a very pronounced feature in this part of the Black Hills, occurring in many places on a far less stupendous scale than about Terry peak. Small and perfect laccolites occur on Two Bit gulch, three miles from Deadwood, and others on Squaw creek, near Carbonate.

The other type of eruptive rock is found in the dykes, which are younger than the great, massive intrusions, and cut both sedimentary beds and the laccolite sheets alike, and it is to these that the ore bodies probably owe their existence. Over the greater part of the region in question erosion has removed a vast amount of material, both of the sedimentary beds and the eruptive rocks. How great the thickness of the sedimentary series originally was has no bearing on the economic features, but it probably included the Permian, Jura-trias and Cretaceous which overlie the Carboniferous. The super-induced erosion which determines the courses of the Belle Fourche and South Cheyenne rivers, which almost encompass the Black Hills, indicates that the Jura and Cretaceous covered the entire country.

As a matter of course, this vast erosion included many ore bodies, and their values, in the case of the telluride deposits at any rate, were irrevocably lost, as these ores form no placers. The uplift, faulting and erosion have spread out the open book of geology here—an epitome of the Rocky mountain region—the primer, I may say, of geological science.

Not only are the sedimentary beds ore-bearing, but the eruptive rocks are known to contain gold. This is true of Two Bit and near the Carbonate Camp, and it will probably be found to be the case elsewhere. Having described the occurrence of these ore bodies geologically, let us make a comparison with Leadville, Colo.

In this district we find essentially the same features as obtain in the northern Black Hills. The limestones are explored for bodies of lead-silver ore and the Cambrian and Carboniferous formations consist chiefly of quartzites at base with limestones above. The succession of rocks in the two districts is not identical, but the geological age is the same and the conditions under which the ore bodies are found are essentially the same. The limestones of the Leadville district are explored for bodies of lead-silver ore, and with what result every mining man knows. More recently exploration for gold in the silver camp has been carried on industriously in the eruptive rocks back of Leadville, on Breece Hill and still higher toward the mosquito range. Mines of phenomenal richness have been and are still being developed. The occurrence of so many conditions in Leadville analogous to the Black Hills region leads the writer to think that a systematic exploration of the underlying quartzites should be undertaken, with a view to the possible discovery of gold under conditions possibly identical with those in the Black Hills. Another fact of importance in this connection is the occurrence of gold in the quartzite at Battle mountain, Red Cliff, not far from Leadville, and this quartzite is positively known to underlie a large portion of the Leadville region.

The yellow silt so characteristic of the Red Cliff deposits is identical in appearance and manner of occurrence with the yellow silt-like deposits in the lower quartzite of the Black Hills, particularly between Carbonate and Garden City.

Should explorations at Leadville be undertaken in this direction, it must be remembered that the silicious telluride ores of the Black Hills invariably lie in close proximity to one of the vertical dykes referred to and that investigations should be carried on with that fact in view. The discovery of gold in Leadville under the conditions mentioned would give a new impetus to the industry which would extend over a period of many years. On the other hand, the Black Hills would perhaps be benefited by a careful exploration of the eruptive rocks in search of more gold-bearing deposits similar to those found in the massive eruptive rocks back of Leadville.

W. H. S.

Some Questions Answered.

What is the best speed for overshot water wheels to get the maximum of power?

What is the best method of getting and keeping copper plates in good working condition when they have been used before and in many places the silver is worn off and the plate seems so hard that the quicksilver will not remain coated on the plate, but runs in globules? The plates in many places are pitted with small holes.

What is the average amount of wood used per ton of ore crushed in a 10-stamp steam mill run by portable boiler and engine—the ore average rock?

Is there a law in this State compelling employers to pay their employes monthly or not?

Quincy, Cal.

The maximum power with overshot water wheels is obtained when they are running at maximum speed with the maximum amount of water which the buckets will carry. A diminution of water results in a corresponding diminution of power. The speed at the periphery of the wheel varies with the load and also with the diameter of the wheel for a given number of revolutions per minute.

Copper amalgamating plates, whether silvered or not, may be kept in condition by dressing twice or oftener daily. The character of water used in the battery has often a bad effect on the plates, necessitating a more frequent dressing. Evidently the plates mentioned have been scraped with a steel or iron instrument with the natural result—the removal of the silver plating, and doubtless acids and cyanide solutions have also been employed to the injury of the plate. When plates become hard from these causes they give much trouble. On pages 36 and 175 of the current volume will be found descriptions of the methods of caring for plates in two large mills.

The amount of wood consumed in a 10-stamp mill varies considerably with the character of the wood and the kind of boiler and much also depends on the judgment of the fireman. An average consumption would be about one-tenth of a cord of dry wood to each ton of ore crushed in a 10-stamp mill. A fire-box boiler, such as described, consumes more wood for work accomplished than a return-flue boiler, such as are set in brick or stone foundations.

There is a law on the statute books of California requiring corporations to pay employes monthly.

A MR. TABER is reported to have perfected improvements on a telephone transmitter, by means of which a person in a noisy workshop at least 40 feet from the 'phone can be distinctly heard at the other end of the line.

Some Very Extensive Claims.

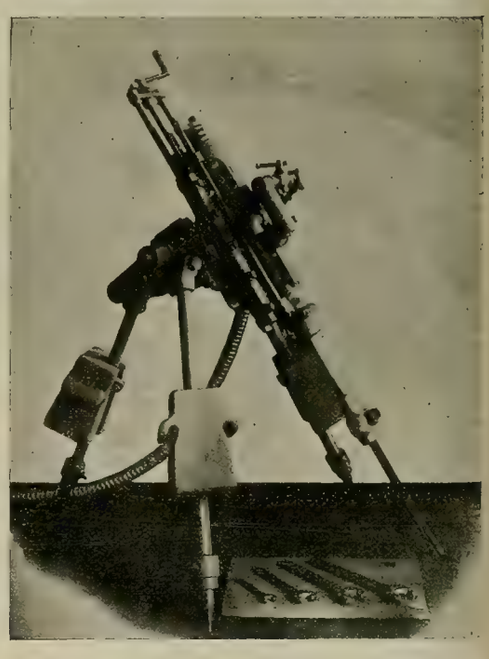
A New York dispatch this week says T. A. Edison, Jr., has discovered a new process for hardening and toughening steel and iron, and that a $1,000,000 company has been formed to float the project, known as the Thomas A. Edison, Jr., & William Holger Steel and Iron Process Co., incorporated in West Virginia. Thomas A. Edison, Jr., claims that his discovery will "revolutionize the iron and steel industries;" that it "will increase the elastic limit and the tensile strength of both iron and steel. It will increase the tensile strength 5% and the elasticity 30%. For instance, I can take a sheet of 10-inch armor plate, such as is used in building the United States war ships, and make it withstand the same force as the ordinary 15-inch plate." The new process will be used in hardening steel nails, frogs for switches, machine shop tools, needles, knives and many articles for general use. We are in communication with the Government for supplying armor plates for men-of-war. We will agree to give the Government plates that will be proof against shell and that will make the vessels much lighter."

Smokeless Powder.

The first smokeless powder that I made in England was made in exactly the same manner as the French. I had obtained a quantity of true guncotton, that is, tri-nitro-cellulose (known sometimes as insoluble guncotton because it cannot be dissolved in alcohol and ether like collodian cotton, di-nitro-cellulose). Some of this powder, when freshly made, produced fairly good results, quite as good as those produced by the French powder, but upon keeping it for a few months the grains lost their transparency, became quite opaque and fibrous, and it then burned with great violence. Investigation showed that about 1% to 2% of the solvent was still in the powder when the tests were first made, whereas the drying out of this last trace of the solvent had completely changed the character of the powder. I then added to this powder about 2% of castor oil, with the result that the castor oil remained after the solvent had been completely removed, so that the powder would keep any length of time—indeed, powder made at that time (1889) is quite good to-day.—Hiram S. Maxim.

Giant Improved Drill.

Herewith is portrayed the Giant improved drill, a rock drill of simple construction, made and sold by



the Compressed Air Machinery Co., 11–13 First S San Francisco, Cal.

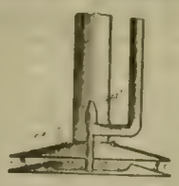
FROM Manila a telegram goes to Hongkong by cable, thence to Saigon in Cochin China, and another cable carries it to Singapore. Around the Malay peninsula it goes by another cable to Penang, an island on the west coast of Siam, and from Penang to Madras. Here it strikes the first land telegraph line and crosses India to Bombay. Thence it goes under the Arabian sea to Aden, under the Red sea to Suez, by another cable to Malta, and still another line takes it to a point in Portugal. From there it is cabled to Land's End in England, crosses the Atlantic ocean to the coast of Nova Scotia, thence to New York and across the continent to San Francisco. It has traveled 17,351 miles.

Latest Mining and Metallurgical Patents.

Patents Issued February 21, 1899.

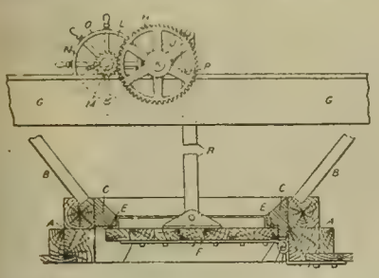
Specially Prepared for the MINING AND SCIENTIFIC PRESS.

APPARATUS FOR COLLECTING GOLD FROM RIVER BEDS.—No. 619,727; Jno. T. Davis, San Francisco.



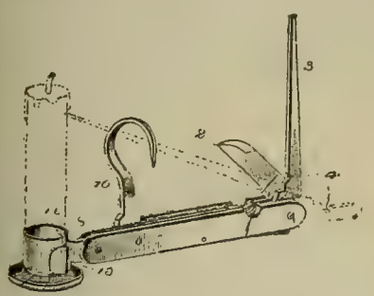
A combination of a boat having an opening in its bottom and a sluice box located adjacent to the opening and provided with suitable riffles; an elevator pipe arranged in opening and having its discharge mouth over the sluice box; a hood carried by the lower portion of the elevator pipe; a pan secured to and separated from the hood, a pressure or delivery pipe entering near the bottom of the elevator pipe and turned upward therein and terminating in a nozzle; a water discharge pipe connecting with the pressure pipe and extending through and below the pan, and a windlass carrying a chain for supporting the elevator pipe to raise and lower it and to permit the addition of sections thereto.

DUMPING DOOR FOR DREDGING VESSELS.—No. 619,-837; Jos. Edwards, New York City.



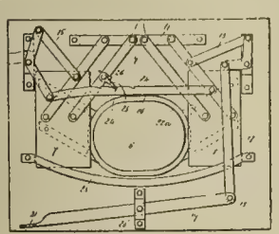
In a dredging vessel, a swinging dump-door having vertically adjustable hinges and elastic packing between the door and its seat, in combination with a vertical connecting rod and a cogwheel having a projecting arm and a motor pinion and hand wheel, whereby the rotating of the hand wheel in one direction will force open the door, and, if rotated in the opposite direction, will tightly close and hold it.

COMBINED MINER'S CANDLESTICK AND FUSE IMPLEMENT.—No. 619,765; J. F. Layes, Lenville, Idaho.



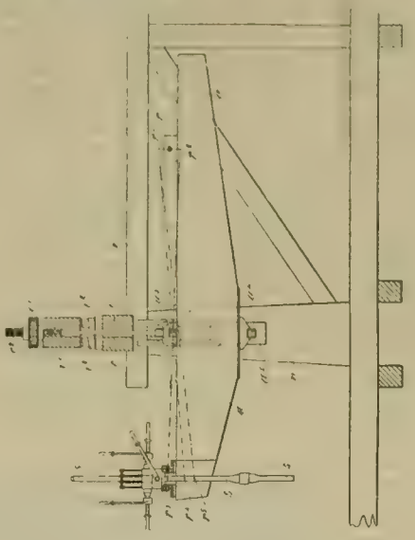
An implement consisting of a handle, a suitable means for supporting the handle, a candle holder attached to the handle and having a cylindrical portion adapted to receive the lower end of the candle, the cylindrical portion having in its side a recess, a sleeve adapted to slip in the lower end of the cylindrical portion, the sleeve having in its side an eccentrically extending section adapted to enter the recess of the cylindrical portion, and a removable drip cup attached by means of a screw to the bottom of the sleeve.

FURNACE DOOR.—No. 619,817; Geo. W. Wolf, Keyser, W. Va.



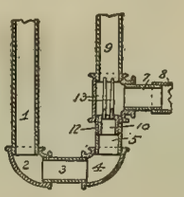
A furnace provided with two similar doors suspended by lever arms, a crank lever supported laterally at each side, one arm of each crank lever being connected by means of pivoted links with the adjacent lever arms, and one arm of one crank lever pivotally connected with a lever arm on the opposite side by a horizontal cross bar; a treadle lever in operative connection with one arm of the opposite crank lever, the crossbar provided with notches or recesses and one of the lever arms provided with a pivoted pawl which operates in connection therewith; a horizontal bar forming a guide for the lower end of the doors.

BORING APPARATUS FOR DEEP BORINGS.—No. 619,907; A. Raky, Rupprechtsau, Germany.



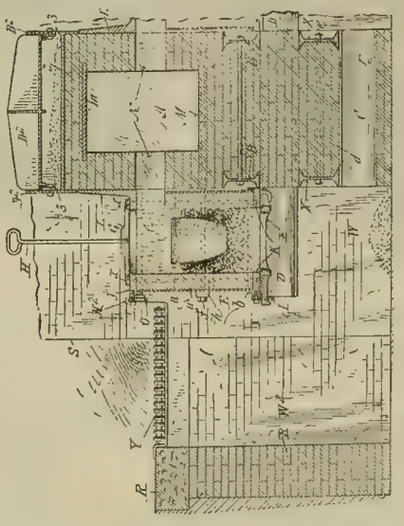
A boring apparatus for deep borings, having an oscillating beam adapted to carry the rods at one of its ends, and to be acted on by the driving power at its other end, and having an elastic support that is put under tension by the weight of the rods, the combination with the latter and with the rods, of springs for maintaining the tension of said support, pins located upon the under crossbar and serving as guides for the springs, arranged in such manner that, in accordance with the increase of the weight of the rods, the number of springs in action may be correspondingly varied.

MINING PUMP ATTACHMENT.—No. 619,938; B. Chaloner, Anaconda, Colo.



In a water-elevating apparatus, the combination with the supply pipe, the discharge pipe and connections and the coupling connected with said discharge pipe, of the suction pipe connected therewith, the screw-threaded plug and the jet pipes extending above the coupling.

CRUCIBLE FURNACE.—No. 619,973; Marsh & Millett, Springfield, Mass.

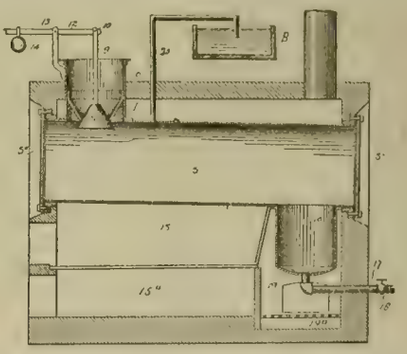


A metal-melting furnace construction, substructure comprising masonry, longitudinal and transverse iron I-beams embedded in masonry, bolts extending through masonry and interengaging longitudinal beams, a superstructure comprising transverse iron I-beams extending across substructure, the extremities of which last-named beams constitute supports for the melting furnaces, a superstructure comprising longitudinal I-beams extending across transverse beams, masonry in which the central portions of transverse I-beams, and portions of longitudinal beams, are embedded extending upwardly and containing a main flue for communication with a chimney, and furnace flues communicating with main flue, iron top frames having a floor covering the top of superstructure and having parts covering upper portion of sides of and having sides extending upwardly from floor, and a series of separated iron boxes for holding metals supported upon frame sides, each having a metal-holding compartment open on the opposite sides of the superstructure.

ORE CONCENTRATING MACHINE.—No. 620,014; O. Blackett, Sydney, N. S. W.

In an ore concentrator, a combination with a downwardly inclined sluice box, of transverse riffle boxes arranged at intervals in the sluice box, screens arranged transversely between the riffle boxes, each screen being arranged to receive the overflow from the riffle box immediately in advance, and means for flowing water down the sluice box, each riffle box being narrower and deeper than the riffle box immediately below, and each screen being narrower and coarser than the screen next below, the arrangement being such that the velocity of the upward flow of water decreases in each succeeding riffle box to suit the varying sizes of the screens.

WURTZILITE PRODUCT AND APPARATUS.—No. 620,-082; C. A. Anthony, Denver, Colo.



A retort having a bottom inclined from end to end and a reservoir depending from there at the low end; with a furnace having a firebox around the reservoir and a separate firebox under the inclined bottom of the retort.

THE fortunate escape of several miners in the Blue Gravel mines in Siskiyou county, California, a few days since, by means of an old shaft, when they had been imprisoned by a cage, illustrates the necessity of having more than a single means of exit from mine workings. As a matter of course, such provision cannot constantly be made for every drift or crosscut, but every mine should have more than one shaft, or be connected with the working of a neighboring mine. There are numerous mines in California which are down 500 and some of them 1000 feet, with extensive workings and only one shaft and no connection with neighboring mines.

AT Madison, Wis., Mr. Wood has organized the idea of thawing out frozen water pipes with electricity, and made two successful experiments. He takes the electric current used for street lights, attaches one wire to the frozen pipe inside the cellar of one house and another wire to a similar pipe in the adjoining or any other house, thus completing the circuit. A current of about fifty volts is then turned on, heating the pipes and melting the ice within. He uses a "transformer" to reduce the voltage, so that the current will not melt the pipes.

A CIVIL ENGINEER of St. Louis, Mo., is advocating the use of crude petroleum on highways, basing his statement, that it creates fine roads and is in the end less expensive than other methods of treating roads, on his observations in the oil regions of Pennsylvania.

The Genesis of Petroleum and Asphaltum in California.

NUMBER V.

Written for the MINING AND SCIENTIFIC PRESS by A. S. COOPER.

Red Shales as Connected With the Genesis of Bitumen in California.—Shales were and are deposited in still and salt water. The iron contained in these waters and organic remains, both animal and vegetable, and other materials constituting the shales were deposited contemporaneously.

If the iron was the peroxide of iron, ferric oxide (Fe_2O_3), by contact with organic remains it was deoxidized and reduced to a protoxide, ferrous oxide (FeO), by the absorption of one equivalent of its oxygen; when the peroxide was reduced to a protoxide, carbonic acid produced by the decomposition of organic matter, then united with the protoxide, forming carbonate of iron ($FeCO_2$).

The carbonate of iron imparts a bluish or greenish color to the deposit.

The accumulation of iron in the presence of an excess of organic matter retains the form of ferrous carbonate. In all coal measures of all periods, whether Carboniferous, Jurassic, Cretaceous or Tertiary, or in all cases where there is organic matter in excess in a state of change—in all strata, whether older or newer, in which there is organic matter in excess in a state of change (not graphite)—the iron is in the form of carbonate protoxide or ferrous carbonate ($FeCO_3$).

Sulphide of iron, ferric sulphide (FeS_2), is subsequently formed and deposited instead of carbonate of iron. The sulphates of lime ($CaOSO_3$) and of magnesia ($MgOSO_2+7HO$), and other sulphates which exist in sea water, when subjected to the action of decaying organic matter out of contact with air are deoxidized and converted into solubles, from which sulphuretted hydrogen gas is set free by the carbonic acid gas produced by the decomposition of organic matter. Sulphuretted hydrogen converts the soluble compounds of iron into sulphide of iron. The color of pyrites is brass yellow.

The presence of protoxide of iron and of iron pyrites in their shale beds arises from the considerable amount of organic substances exercising a reducing action. The water flowing from the mountain heights where there are no organic substances exercises at first an oxidizing influence, in virtue of which the rocks over which they flow are decomposed.

The suspended substances carried down by these rivers and the detritus swept along their beds come after a time in contact with organic substances, by means of which the peroxidized iron compounds are again reduced. Consequently the iron thus carried into the sea is for the most part in the state of protoxide, either combined with silica or with carbonic acid, the silicate being suspended and the carbonate dissolved in the water.

When unaltered by oxidation the carbonate of iron, with varying amounts of lime, clay or sand, is dark grayish blue or green, or even white, in color.

When unaltered by oxidation the sulphide of iron is brassy yellow in color.

From the preceding explanation it is safe to say that, at the time of their deposition, the carbonaceous shales were not red; and as long as they are not submitted to oxidizing influences they will not become red.

When carbonate of iron is exposed to the oxidation of the air it forms limonite (hydrous ferric oxide), which is usually of a brownish yellow or brownish red color. These iron ores are found in all stages of transformation. On the outcrop they are limonite; under dense cover, carbonate; while going from the outcrop inward the limonite constantly decreases in proportion to the carbonate. In the alteration of the compact carbonate the line of chemical change and color is usually very sharply defined, and the limonite covering can often be entirely removed from the enclosed core of carbonate by a blow with a hammer, the limonite covering preventing the carbonate core from being oxidized by the air. In shales charged with gray carbonates of iron the following reaction takes place by the action of the air: the carbonic acid is released and part of its oxygen oxidizes the iron.

Gray shales containing finely divided pyrites or bisulphide of iron are converted by heat into bright red, the sulphur being released, leaving the shales charged with red oxide.

The color of burnt ferruginous shale is entirely due to the amount of iron present. Gray shales containing less than 1% or 1½% of iron change by heat to various shades of cream color or buff; while those containing 2% to 10% or 12% of iron produce by heat pink and bright red bodies. The depth of the color depends merely on the amount of iron present, the buff shades graduating into the deeper shades of red.

A group of stratified rocks usually consists of various species arranged in alternating beds, a series of beds of many hundreds or even thousands of feet in thickness containing strata of shale, limestone or sandstone.

Some strata are seamed or porous and easily penetrated by fluids, serving as conduits and reservoirs for fluids. Some strata are nearly impervious to fluids, while others are practically so, frequently serving as incasements for the conduits and reservoirs formed in and by porous and seamed strata.

All stratified beds have been originally deposited in a horizontal position, or approximately so. While these beds were in the horizontality of their deposition and incased by impervious strata, there was little or no circulation of fluids within their porous or seamed strata. When they were tilted and inclined to the horizon at angles varying from the horizontal to nearly absolute perpendicularity and their porous and seamed strata exposed to the entrance of fluids by denudation fracture or otherwise, and an exit for the fluids was supplied or produced at a lower level than the place of its entrance, the circulation of fluids commenced, slowly at first and gradually increasing as the inclination and exposure of the different strata became greater. The course of the circulating fluids was complex and anfractuous.

Water supplied by the rainfall of the region enters at the outcrop of the porous and seamed strata. If the porous and seamed strata are incased in impervious strata, the greater the depth to which the strata extend from the place of entrance of the water, the greater the pressure will become. In some instances this pressure will be very great, forcing the water into comparatively impenetrable rocks.

The water percolating and circulating through the porous and seamed strata, by its solvent action, accumulates mineral ingredients. These waters, saturated with minerals, coming in contact with other minerals existing in the shales, by chemical reaction produce heat. This heat contracts and fractures the shales, permitting a freer circulation of water.

This chemical heat distills petroleum from carbonaceous shales and oxidizes the carbonate and sulphide of iron, producing the red colors of the shales, and water of different temperatures charged with mineral ingredients will frequently rise by hydrostatic pressure through fissures and faults, etc., to the surface of the earth, forming mineral springs. These springs are often accompanied by bitumen and their solvents, action producing the white shales hereafter described.

But very few fossils exist in these red pyrogenous shales, as they have been obliterated by the solvent action of hot water or by the chemicals held in solution by the circulating waters; or, if the molds or casts of their external forms existed, they have disappeared from the same causes, or they have been crushed and distorted beyond recognition.

Red Shales in California.—Red shales in California are the effects of chemical heat. Strata which have been more or less altered by the action of heat, emenating in the strata from chemical reaction, consists of burnt shale, porcelain jasper, earth, clinkers, slag and white shale.

OUTCROP OF RED SHALES AND PORCELANITE.

Burnt Shale.—Its color is usually red, sometimes gray, yellow or brown, and graduating from cream color or to brilliant red. It is clay or shale burnt, but not so much changed as to form a porcelaneous mass.

Porcelain Jasper.—It is shale, or changed into a kind of porcelain by the action of heat. It is dark red, yellow or striped yellow and red.

Earth Clinker or Slag.—This is a shale converted into a kind of clinker or slag. It is black-brownish or reddish, and it has occasionally a tempered steel tarnish.

Sometimes it shows iridescent colors. It is vesicular, usually amosphous, but occasionally possessing the prismatic form of artificial coke.

White Shale.—During these chemical fires, carbonic acid, sulphuretted hydrogen and aqueous vapors are formed; these exhalations, in passing through the shale, bleach and decompose it. The silicates are decomposed by the continuous action of aqueous vapors at 212° Fahr., sulphuretted hydrogen, air and the alkalies, magnesia and lime, are nearly removed, and metallic oxides are carried away. The vapors convert the shale into a white clay, or nearly white, when a small quantity of iron still remains. By the removal of the alkalies, magnesia, lime and metallic oxides, the quantity of alumina and silica increases. The absence of the bases, such as lime and iron, in these bleached shales give growth to a different vegetation from that which grows where these bases exist. This difference in vegetation is a good index to deposits of petroleum and bitumen. The removal of these substances make the shale incapable of sustaining vegetable life; the absence of or scarcity of vegetation is indicative of this action. Immense beds of these white and altered shales frequently occur in the vicinity of bituminous deposits, generally running in the direction of the anticlines.

From the immense amount of mineral matter which has been carried away by the solvent action of water, thousands of tons of fossil shells, silica, magnesia, iron, etc., and the large area now occupied by the whitened shales, the flow of mineral water at some former time must have been very copious as compared to the flow at the present time.

The illustration shows an outcrop of red shales and porcelanite near Mount Solomon, Santa Barbara county.

Mine Management.

TO THE EDITOR:—In your issue of Feb. 11th, "Mine Superintendent" treats the general subject of mine management in a sensible way. His letter should be read by every one in any way connected with mines. One point not covered in his letter seems worthy of consideration, and that is what may be termed the "treasury influence" upon the management. A mining property should be looked upon as a business entity and the superintendent should manage it solely from the standpoint of the mine's best interests. How many superintendents are privileged to do just that? How many superintendents have spoiled promising mines and their own reputations, not from choice, but at the behests of a hungry treasury?

Men of good ability run "grass root tunnels" to catch the ore quickly, rob the mine by gouging the good ore, stop development to avoid expense, realizing all the time that they are open to the sensible criticism of their own employes, but compelled to the course by the demands of the treasury. Verily, a large but hungry vein is more to be desired by the average superintendent than a large and hungry stockholder. More good mines are closed because the superintendent manages them from the standpoint of an abused treasury than because of his lack of skill and good sense. MINE OWNER.

THE Liverpool Chamber of Commerce is favorably considering a proposition to build a "mono-railway" between that city and Manchester, over which trains are to run at a speed of from 100 to 150 miles an hour. B. Behr, the advocate of the scheme, claims that the new system will obviate the ordinary dangers of railroad travel. Derailments are an impossibility, and there will be fewer collisions than in the two-rail system. The cars intended for the line are to be fitted with wheels in the center, and these will run on an elevated rail. The position of the coach on the railway may be likened to the saddle packs which hang on each side of the camel's back.

THE *Journal of Geology* is authority for the statement that a new mineral has recently been discovered which, as a fuel, is far superior to coal. The substance, which is of a lustrous black color, is found on the island of Barbadoes and is called by the natives "manjak." It is thought that manjak is petrified petroleum, great quantities of petroleum being found on the same island. It contains only 2% of water and fully 27% of solid organic matter, thus surpassing in utility the best asphalt of Trinidad, in which 30% of water is contained, and which has been classed so far as the finest fuel.

A LARGE map of the Cripple Creek mining district, situated in El Paso and Fremont counties, Colorado, issued by the *Mining Investor* of Colorado Springs, has been received. Upon it are shown several thousand of the claims located in that region. Around the richest portions of the district the claims lie thickest, overlapping each other, sometimes five or six deep. The map graphically illustrates the possibilities under the mining laws of the United States for interminable litigation.

The Auto-Truck.

Written for the MINING AND SCIENTIFIC PRESS.

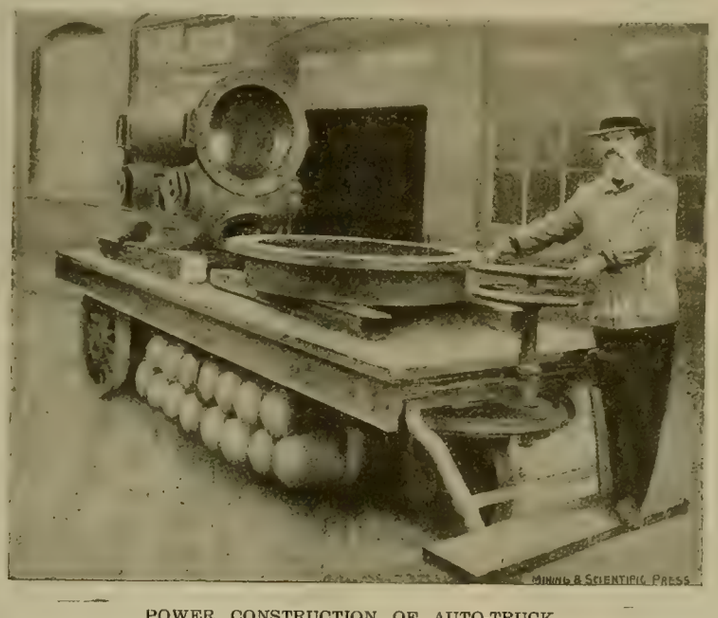
Several illustrated articles have recently appeared herein, descriptive of "automobiles," "auto-trucks," "horseless carriages," and other forms of motor designed to supplant the horse on the streets and roads. Universal present interest attaches to the new devices with that end in view. In the great cities men who make their living by the transfer of material naturally decry the several inventions; but, if the new system can prove to be economical, their protests will prove as futile as have those of workers in other industrial fields.

In the city of New York has recently been formed an "Auto-Truck" Company, that proposes to supplant the 17,000 truckmen who now make their living by hauling goods. The new company has a capital of $10,000,000. They are building trucks which, they claim, can be severally run for twenty-five miles with one charge of compressed air at a minimum cost of 1 cent per mile. A similar corporation has been formed, with equal capitalization, in Philadelphia; another in Chicago, and so on. Probably when all these big concerns get going, they will form a truck trust, as nearly all other industrial organizations are doing at present.

The proposition is to build power stations at various points throughout the city, a system of pipes connecting with these stations to be laid beneath the streets. These pipes will connect with hydrants, similar in appearance to water hydrants. A truck will stop, make connections, and, in two minutes, steam already used in the working cylinders. After leaving the high-pressure cylinder, the air is again warmed by causing it to flow through pipes in the hot water heater. Again hot water is sprayed into the pipes containing the air, before the latter passes to the low-pressure cylinder. In this, it is found that the results of reheating are slight in comparison with those in the high-pressure cylinder. So perfect, yet simple, is the mechanism throughout, that the valves respond instantly to their requirements. There is also a hand valve, in the same pipe as the automatic water valve, that enables the amount of water to be adjusted as may be thought expedient. On small trucks, the heater will be dispensed with; and, eventually, when greater perfection is reached, it will not form a part of the larger trucks.

One of the advantages of the Hoadley-Knight motor, as the New York auto-truck is styled, over the old style air-motors is that there is no exposed machinery. All of the moving parts of the motor proper run in a cast iron box, or casing, which is partly filled with oil. They are thereby continuously lubricating themselves. With this system, oil cups are unnecessary. After a careful estimate, it has been found that, during service, about 35% of the indicated power of the compressor is delivered at the axle in driving the motor, and of the total amount stored, about one half is available in the motors. If it were not for the reheater, this would be reduced by at least 50%. It has been proved by tests that the cost of reheating is about one-fifth of the cost of compressing the air.

The auto-truck is absolutely under the control of the motorman, who sits on an ordinary wagon seat. The steering apparatus is similar to that of the yard



POWER CONSTRUCTION OF AUTO-TRUCK.

will be replenished with compressed air. The conduits beneath the streets will be ordinary iron pipes, 2½ inches in diameter, while the pipe which supplies air to the truck will be about ½-inch in diameter. Together with these may be laid two other pipes—one for water and the other for steam—for purposes yet to be explained. The air bottles, or tanks, varying in number according to the size of the truck, are placed beneath the floor, between the two axles. These air reservoirs are seamless steel bottles. An average truck requires nine of these bottles, placed in the manner shown in the accompanying picture of a heavy yard truck. In a wagon truck these reservoirs are fewer than in a yard truck, higher from the ground, and out of all danger of being damaged. The motor is iron-clad, and rests in the middle, on the rear axle, and is driven in the middle by means of the gear. This does away with the side rods of the old-style air motor, prevents indirect swaying, and is considered a great improvement. A heavy truck has a heater under the center of the floor, which consists of a seamless steel flask charged with hot water, under a pressure of from 150 to 300 pounds per square inch, heated by steam at the same time the air reservoirs are being filled at the charging stations en route. A pipe leads from the air reservoirs to a combined reducing and throttle valve, which lessens the storage pressure to the working power. But before the pipe reaches the reducing valve it passes several times around the heater, so that the air can receive sufficient heat to prevent the freezing of any moisture that may be in it. When the air is reduced to about 320 pounds of pressure per square inch, it passes through a coiled pipe placed in the reheater, which raises the temperature of the air, causes it to expand, and naturally increases its working capacity. Again, before this air goes into the high-pressure cylinder, hot water is injected into it by the opening of automatic valves. A part of this water is instantly vaporized, and takes the place of the truck, two horizontal wheels, one below the other. The upper wheel is the controller. On the auto-truck, the controlling and steering apparatus will have the appearance of that on an automobile carriage. The motor is controlled by varying the cut-off, also by the throttle, the two being operated simultaneously. A forward movement of the single controller starts the truck, and the propelling force is proportional to the distance it is moved from the starting point, so that any degree of quickness can be obtained. A backward movement to the starting point brings the valve to a minimum cut-off, and closes the throttle; while a still further backward movement reverses the motor and opens the throttle to back the truck. No brakes are required, and the truck can be brought to a standstill at a moment's notice. It is claimed that, while a horse finds it difficult to drag a load of two tons, the auto-truck will move easily along with five times that load, at the rate of eight miles an hour, to a horse's four miles. It is also asserted that the auto-truck can turn almost in its own tracks.

The tires of the heavy trucks will be of steel, while those of the lighter ones will be of cushion rubber. No improvements will be made on the main body of a truck, which will be similar to that of trucks drawn by horses. Each truck, complete, will cost from $2000 to $3000. That includes all the expense of the truck, and there is very little wear or tear to take into consideration; while the cost of running is about two-thirds of that of a horse and truck. The auto-trucks are unfit for country use, and can only be utilized where there are excellent roads, and where replenishing stations can be established.

At Trenton, N. J., on the 23rd ult., were filed articles of incorporation by the New York Electric Vehicle Transportation Co., with an authorized capital of $25,000,000, to manufacture and operate vehicles propelled by electricity, air, gas and oil.

Conglomerates in Honduras.

Written for the MINING AND SCIENTIFIC PRESS.

There are in the Department of Olancho, Honduras, C. A., auriferous gravel deposits of considerable extent, particularly in the territory drained by the Guyape and Parnal rivers. The beds are not of great thickness—some places 200 feet, but usually much less. The gravel lies on a formation of red sandstone dipping at low angles, having been gently folded, and possibly also faulted, over quite a large area. Intercalated in these red sandstones is a series of conglomerate beds, in some of which the fragments are angular (breccia) and in others well worn by water. In the crystalline rocks which occur in the neighborhood quartz veins are not abundant, though not unknown. The gold found in the gravels is uniformly in small grains, coarse pieces rarely being found. These facts, well known to the writer, have led to the thought that the conglomerates may be auriferous and are possibly the source of the gold found in the gravels. Structurally, these sandstones and conglomerates are much like those in the Witwatersrand, South Africa. It must not be understood that it is positively asserted that these conglomerates are gold-bearing, but there is a reasonable probability of it. Near the Guyape river, at its confluence with the Guampo creek, about 200 miles from Brewer's lagoon by the river, are also found large conglomerate deposits intercalated in red sandstone. The deposits, so far apart, may be in the same geological horizon, but it would require a great deal of time to determine this, as the latter locality is in a dense virgin forest, amid rugged hills, though easily accessible from the coast.

Wireless Telegraphy.

There are several methods by which electric or magnetic effects can be utilized for telegraphy without the use of a continuous wire between the two stations. One of the most simple, in the form in which it has been put into practice by the officials of the postal telegraph department, consists in making an interrupted or alternating current in one line or circuit. At some distant place there is a receiving line or secondary circuit in which a secondary electric current is generated by magnetic induction across space. The secondary current is detected by a suitable sensitive receiving instrument and can be made to give rise to appropriate signals. This method has been put into practical operation by the British post office between Lavernock and Flat Holm, on the Bristol Channel, over a distance of three or four miles, and is now in daily use for sending messages. The other method, which has attracted popular attention, is based on the employment of Hertz waves, and has been especially developed by Marconi.

In this wave system a long insulated upright rod or wire is erected at each of the terminal stations. At the sending station an induction coil with spark balls is connected between the bottom of the rod and the earth, and at the receiving station a very sensitive detector, consisting of a Branly tube or tube containing fine metallic filings is inserted between the upright rod and the earth. When the induction coil is in action rapid electrical oscillations are made in the transmitting rod and ether waves sent out from it. These on reaching the receiving rod set up an electromotive force in it, which causes the metallic fillings in the detector tube in connection with the rod to become conductive. By means of a relay and battery this electrical change in the detector can be made to print Morse signals on a strip of paper utilizing the ordinary Morse instrument.

Aerial Bombardments.

The regions of space beyond our planet are filled with flying fragments. Some meet the earth in its onward rush; others, having attained inconceivable velocity, overtake and crash into the whirling sphere with loud detonation and ominous glare, finding destruction in its impervious armor, or perhaps ricocheting from it again into the unknown. Some come singly, vagrant fragments from the infinity of space; others fall in showers like golden rain; all constituting a bombardment appalling in its magnitude. It has been estimated that every twenty-four hours the earth or its atmosphere is struck by 400,000,000 missiles of iron or stone, ranging from an ounce up to tons in weight.

Every month there rushes upon the flying globe at least 12,000,000,000 iron and stone fragments, which, with lurid accompaniment, crash into the circumambient atmosphere. Owing to the resistance offered by the air, few of these solid shots strike the earth. They move out of space with a possible velocity of thirty or forty miles per second, and, like moths, plunge into the revolving globe, lured to their destruction by its fatal attraction. The moment they enter our atmosphere they ignite; the air is piled up and compressed ahead of them with inconceivable force, the resultant friction producing an immediate rise in temperature, and the shooting star—the meteor of popular parlance—is the result.

The Alluvial Deposits of Western Australia.*

By T. A. RICKARD, State Geologist, Denver, Colorado.

General Geological Considerations.—The interior of West Australia is an arid table land, elevated 1400 feet above the sea. This plateau is flanked to the south by the Tertiary limestones which fringe the Great Australian Bight. It is bordered northward by the Carboniferous beds of the Fitzroy river and westward by the granite of the Darling hills, while to the east this wide area, about 900 miles square, slopes downward imperceptibly into an undulating plain of sand, which stretches with dismal persistence across the boundary of South Australia. The waters of the ocean receded from this tract of land long ago; it is probably the oldest land surface on the globe, and represents the basal wreck of a much larger continent. Herewith is presented a map of this region.

The Coolgardie and Kalgoorlie gold fields are situated in the southwestern part of the region. The rock formation consists of granite penetrated by diorites and andesites. The latter are occasionally associated with tuffs, which have been readily mistaken for sedimentaries. There are no fossil-bearing rocks, such as would afford a datum-line from which to measure the relative geological age of the prevailing formation. On the extreme edges of the mining territory there are, it is true, remnants of sand rock which are considered identical with the "desert sandstone" of Queensland, determined by Daintree to be of Mesozoic age. But even this formation has evidently been laid down so long subsequent to the underlying rocks that it serves merely to emphasize their much greater antiquity. Their age can only be vaguely described as Archæan.

In this region all diversity is wanting, and a sameness of aspect wearies the observer. In the absence of an elevatory movement, more than sufficient to balance the slow degradation of the higher parts of the region, there has been no compensation for the effects of atmospheric erosion, so that this tract has become a dreary flat, strewn with the sandy wreck of weathered rocks.

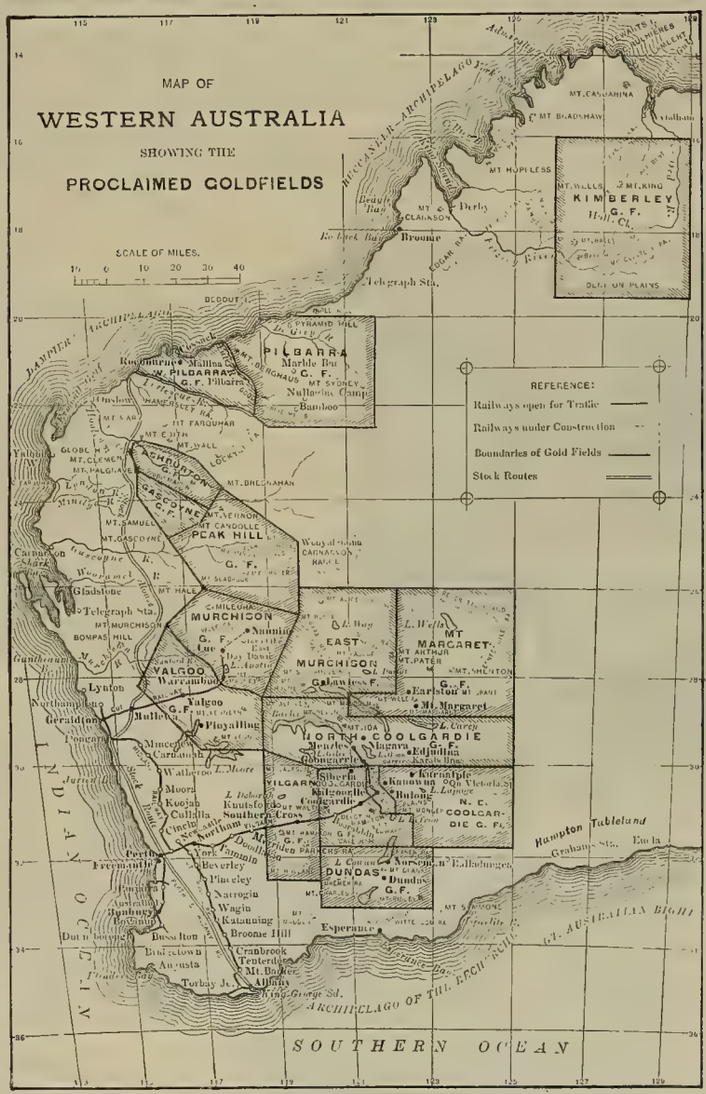
The interior of Australia can be likened to the great basin, occupied by Nevada and parts of Utah, Idaho and Arizona, between the Rocky mountains themselves and the Sierra Nevada. There is only one large river in Australia which reaches the sea, namely, the Murray, which rises near the boundary line of Victoria and New South Wales, and then flows toward the interior, to be saved by a backward sweeping curve, which permits the river at length to empty itself into the sea at the border of South Australia. There are many "lost rivers," like the Carson and the Humboldt in Nevada. During the rainy season they are tempestuous torrents; during the succeeding dry months their course is marked by sandy bottoms, dotted with an occasional water hole. The mountains are near the coast, so that the Australian Alps and the Blue mountains do the same service as the Sierra Nevada and the Cascades, in that they interrupt the warm, moisture-laden winds and compel them to precipitate on the seaward slope. The consequence is that the eastern parts of the colonies of Queensland, New South Wales and Victoria, between the mountains and the sea, resemble the valleys of California and Oregon, just as the interior region beyond them bears a likeness to the dry tracts of Nevada and Arizona.

The sea retired from the interior of West Australia in the very dawn of geological time, and the movement of elevation which raised the land above the waters continued with but little interruption until the beginning of the Tertiary period. Since then slow subsidence has robbed the Australian continent of a part of its extent and made Tasmania an island. There is evidence of a much larger continental area, which at one time extended toward southern Africa.

The main drainage of the interior is to the south. The last retreat of the sea was accompanied by the formation of broad valleys, which have lost their former outlines and now appear as long depressions, largely filled up with the products of erosion.

The Physiography of the Gold Fields.—The principal gold field of West Australia is situated in the southwestern part of the desert plateau. The chief towns are Coolgardie and Kalgoorlie; they are twenty-five miles apart, and are connected by 350 miles of railway with the coast. During 1897 the total rainfall amounted to $5\frac{2}{5}$ inches at the one place and $4\frac{3}{4}$ inches at the other. In contrast to these figures, it may be added that the rate of evaporation in this region is estimated to be equivalent to 7 feet per annum.

The country consists of a sandy plain, the monotony of which is intensified by a series of alternating low rocky ridges and equally slight depressions, having a northwesterly direction. Most maps indicate the occurrence of lakes and the occasional course of a stream, but these are the mirages of the cartographer. The "lakes" are shallow basins with clay bottoms, in which, during the rainy season, a little water lingers, and the "streams" are sandy channels, where sinking will sometimes tap a trickling flow of brine. The surface is devoid of vegetation, except in spring, when flowers of a brilliant hue leap into brief existence.



The real nakedness of the region is hidden by the "bush," consisting of scrub from 20 to 60 feet high, chiefly mulga and ti-tree, both acacias. The roads are cut through it with the monotonous regularity of a canal. One portion of the journey is but the counterpart of another. The sameness is wearisome beyond words. And when an elevated spot is attained, the eye commands, from north to south, from east to west, one dark unbroken sea of trackless bush.

Gold mining caused this desert to be invaded. The first discovery was made by Anstey in 1887 at Yilgarn, which is 210 miles east from Perth, the capital of the colony. This started the Southern Cross mining district. Prospectors began to scatter farther inland. In 1892 Bayley made the discovery which marked the birth of Coolgardie and the commencement of an activity which culminated in the mining excitement of 1895. A series of rich finds, scattered over the surrounding desert, gave rise to the settlements of Menzies, Goongarrie, Kanowna, Kurnalpi, Kunanalling, Wagiemoola and a score of other patches of corrugated-iron hideousness labeled with euphonious aboriginal names. In June, 1893, Patrick Hannan pegged out a discovery claim at Kalgoorlie, twenty-five miles east of Coolgardie. The find which he made was of no particular importance, and the neighboring area, like many others, became the scene of the purposeless digging which was at that time sufficient to give an impetus to a great deal of reckless company promoting. However, just as in Colorado, the Mt. Pisgah fiasco of 1884 preceded the real development, eight years later, of Cripple Creek, so the vagaries of irresponsible schemers led to the accidental opening up and the eventual recognition of the magnificent series of rich lodes that have now placed Kalgoorlie among the few great mining camps of the globe.

In 1897 West Australia produced 674,993 ounces of gold, to which Kalgoorlie alone contributed 306,000 ounces. During the same period the mines of the colony paid $2,400,420 in dividends, and out of this total Kalgoorlie is credited with $1,775,000. The growth of the industry is exhibited by the accompanying statistics:

Year.	Kalgoorlie. Ounces.	West Australia. Ounces.
1895	36,000	231,513
1896	103,000	281,265
1897	306,000	674,993

It is estimated that the yield of the colony for the current year will reach a million ounces, and that of this one-half will come from the Kalgoorlie district.

The development of a group of very rich telluride lodes amid this immense desert country, dotted over with the unhappy failures which were based on small pockets of specimen gold quartz, did not happen without a sad expenditure of money and human life. With the whisper of every new discovery, crowds of reckless gold seekers plunged madly into the outer desolation. Eager horsemen jostled the awkward camels, whose swinging gait carried them in turn past the mobs of diggers who trudged wearily to the scene of each successive excitement. One knows not whether to admire the pluck or to deride the foolishness of men who died of thirst and perished of fever in the mad search for gold. The incident known as "the Siberia rush" will be typical of early days. A man came into Coolgardie one night with a story that gold had been found at a locality thirty odd miles to the north. Hundreds started off on horses or on camels; many went on foot, carrying their billies—a tinned-iron vessel of from two to four quarts capacity, in which the miner makes his tea and does his cooking—and blankets upon their shoulders or trundling their packs in wheelbarrows. Some took the wrong direction, and of these many never reached their destination, but died miserably in the bush. Four hundred eventually reached Siberia. This locality has a mean annual temperature of 78° and the summer heat is 112° to 120° in the shade. The only water near the discovery was a soak, a morass of the desert, where water has accumulated in a depression, and is got by digging through the sand which covers it. This soak is seven miles distant. It was soon drained dry by the crowd of diggers. News came to Coolgardie that a water famine was imminent. The superintendent of water works—a government officer—instantly dispatched a dozen camels to the succor of the adventurers. In the meantime, realizing the impending danger, they had left the gold and were making for the nearest condenser. All the drinking water is the product of the "condenser." Many died on that return journey, and many more would have been lost save for the water brought by the camel train. But in a few days there was another stampede in another direction. Thus the gold fields were opened up.

The peculiar character of these "rushes" is directly traceable to the nature of the gold occurrence. Gold is found lying on the top of the ground, and the first surface mining yields extraordinary profits. The search for the particles of gold scattered over the surface is called "specking." In the early days hundreds of ounces were thus picked up in a few hours by the men first to reach a rich spot. When the cream has thus been skimmed off, the sandy soil underneath is treated, the dirt being winnowed by pouring it from one pan into another. After that, actual digging begins, the shallow deposits being trenched and pitted in the search for those patches of rich ground through which the gold is found sporadically distributed. "Specking" is still a recognized occupation on Sundays, even at the established mining centers. Sunday labor is generally forbidden throughout the Australian colonies; hence the opportunity to go "specking," as above described. I have seen as many as 100 men walking about with their hands in their pockets and their eyes intent on the ground, for all the world as if they were in disgrace. A five-ounce nugget may be found; and everyone hastens to the spot. Perhaps nothing more is picked up; or it may be that sufficient gold is discovered to attract troops of "dry-blowers" to the place. The "dry-blower" is brother to the "gulch-miner" of America and the "alluvial digger" of the eastern colonies of Australia. In the investigation of the methods of the dry-blower and the occurrence of the deposits out of which he wins the gold, I observed many facts of such interest, it seemed to me, as to warrant the preparation of this contribution.

(To be Continued.)

* Condensed from paper read before the Am. Inst. M. E.

Mining Summary.

ALASKA.

The Alaska Treadwell report for February hows 21,925 tons ore worked and 444 tons sulhurets treated, latter yielding $15,527. The ullion shipment was $50,504, the ore averging $2.30 per ton. February expenses were 26,444.

Thanksgiving creek, near Eagle City, is one f the latest discoveries on American terriory. A new district is being organized there. Cleven hundred men are working Forty-mile nd tributary creeks.

Eagle has a population of 600, and 140 men re working American creek. Seventy-mile own his forty cabins, and 250 men are workng that creek and its tributaries. The best roducer is Garney creek, from which five en took $8000 last summer.

The Klondike miners are objecting to the harges made by the Pioneer Tramway Co., which the Yukon Council granted a franhise for a toll road to the Bonanza mines. he company took possession of the trail, made ome improvements, erected tollhouses and egan collecting money for every passenger nd pound of freight. The Bonanza claim wners along the tollroad are required to pay or walking over their own claims.

ARIZONA.

Fifteen cases of smallpox are reported mong miners at Clifton.

Shipping ore is being taken out of the Union ine, twenty-five miles southeast of Prescott, hich carries over $300 gold per ton; the mill-g ore carries $40 gold per ton. The vein is 2 et wide.

Kier and Gerritt, two prospectors, have ound a 4-foot vein in the Hualapi mountains, outheast of Kingman. The ore is said to be silver.

H. W. Blaisdell, Shultz, Pinal county, has a ontract with the Mammoth-Collins G. M. & M. Co. for the tailings at the mill other than he 200,000 tons contracted for by the St. ouis Gold Saving Co., who are represented y Peck & Anderson. He will build a cyanide ant below that of the St. Louis Co. The ar says the St. Louis Co. has been clearing 00 a month since early in August last, after aying royalty to the Mammoth-Collins Co. nd they have a few years work ahead of em to clean up what remains of the 200,000 ns of tailings.

In the Grand canyon of the Colorado is reorted a copper ledge. The ore is base and he ledge is said to be 100 feet in width. It exposed in vertical depth for fully 800 feet. he ledge lies on the north side of the river, ne north of Ash Fork.

A copper strike is reported in the Corville ine located twelve miles northwesterly from lobe. The Corville is one of a group of four. he tunnel continued until 180 feet was eached, when a body of carbonate ore was ruck in porphyry and quartz. Running with is carbonate is a 6-inch vein of copper glance e. The crosscut has reached under the dge 225 feet.

On the opposite side of this high ridge or ountain the owners of the Finletter group e driving a crosscut, now in 120 feet.

The surface of all these claims is covered ith ore, broken from the ledges that crop t.

In the Pacific mine, near San Carlos, it is reorted a 5-foot vein of solid copper ore has een found.

Fitzsimmons & Ware have a lease on the aqua Hala mine and mill, employing fifteen en.

P. J. Quinn has leased the Golden Eagle ill.

At the Old Dominion, near Globe, one of the 5-ton furnaces was blown in Feb. 6th with a ew crew of men, who are becoming familiar ith their work, and things are now moving hoothly. A track has been laid for slag pots nd horse power will be used to move them. he new 250 H. P. engine will not be in place. he pump for the mine is now in the shaft nd will handle the water at a depth of 2000 et. The mine is now down 1000 feet.

The Tucson *Star* reports that the Mammothollins G. M. Co. proposes to increase its amps to 100. The water of the Aravaipa ver is to be utilized to generate electric wer for the works.

The Yuma *Sentinel* says that every availble team in Yuma county has been engaged haul the Blaisdell mill and cyanide plant om Picacho to the King of Arizona mine, a stance of forty miles. The plant weighs 400 ns and will be moved as rapidly as possible.

Mojave *Miner*: A. E. Vandercook, associed with R. G. Eckis and B. Vandercook, has und in the January claim near El Dorado nyon a body of ore running well up in gold nd silver.

Mojave *Miner*: There are forty tons of ming machinery at the Kingman depot awaitg transportation to El Dorado Canyon to be ed in erecting a cyanide plant to work the ilings from the El Dorado Canyon mill. The ant will handle fifty tons per day. Mr. ckis is Gen. Supt.——Harris & Redman rently arrived from the Colorado river bringg sixty ounces of gold nuggets worth $18.50 r ounce as the result of three weeks' work. he smallest piece weighs not less than 25 nts.——F. L. Smith, who has mines at Bounry Cone, San Francisco district, has opened a vein of ore, a 4-foot crosscut not yet havg cut through the ledge.——There has been id $18,000 in cash, through the Kingman nk, for the Mollie Gibson and Bullion-Beck, joining mines, at Chloride by E. J. Carter Chicago. The new owner will erect a mill d boarding-house, and the local paper says ill put 100 men to work immediately.——T. cNeely of Mineral Park is shipping ore from s lease on the Retort mine.——M. W. Henkle s made another strike on his Retort mine, ineral Park.——Phillips & Dominguiz are nning a drift from the old shaft on the Daisy White Hills to a block of ground on the 'Malley lease.

CALIFORNIA.

Amador.

Supt. W. R. Thomas has let a contract to sink the shaft at the Central Eureka mine 300 feet, making it 1400 feet.

Record: Water has been turned into the new reservoir of the Wildman-Mahoney Co. It is proposed to build another reservoir in close proximity to the present one.

Butte.

The Oroville *Register* says the dredges now running in the gravel deposits south of that town are taking out from $150 to $300 for each twenty-four hours—for each boat. In some instances the returns exceed these figures.

Calaveras.

J. A. Campbell of Sheep Ranch and Mr. Elliot have discovered a rich quartz vein near the Italian ranch, on the San Antone and O'Neill's creek ridge, three miles southwest of Sheep Ranch.

El Dorado.

Thirty men are employed at the Goglns mine on the Ralston Divide, six men at the Lynchburg and four at the Ramsey City.

Fresno.

The Copper King mine near Clovis is reported capitalized in London for $1,750,000, a company being organized there to work the mine. The Fresno *Republican* says the property was bought some time ago for $15,000. There are twenty men employed at the Copper King mine. The daily output is about fifteen tons.

H. B. Vercoe has bought the Heiskell copper mine, six miles north of Clovis. The property had been abandoned fifteen years ago because it did not pay to work it on account of the low price of copper. There are five men erecting buildings and getting everything in shape to begin active operations.

Kern.

The owners of the Ruby mine, at Randsburg, are shipping from twelve to sixteen tons of ore per day. This is the claim on which C. Koehn recently had a lease, during which he milled over 215 tons, which brought him from $12 to $15 per ton.

A party of four dry washers from the Summit district, twelve miles from Randsburg, have recently brought into that town between $800 and $1000 in gold dust, as the result of a month's work.

G. Otis of Redlands has bonded the Hard Cash mine east of Randsburg.

The new mill recently built by the Union Iron Works of San Francisco, Cal., is in successful operation.

Randsburg *Miner*: B. F. Myers has bonded for ninety days the "9-Spot" mine near the Minnehaha to V. Smith.

Los Angeles.

The Red Rover mine at Acton is being operated successfully under the superintendency of W. R. Shilling. The shaft is to be straightened and sunk to 1000 feet. A new hoisting plant will be put in and the mill enlarged to twenty-five stamps.

At Newball is reported an oil well throwing oil at the rate of 600 barrels daily: the flow of gas and oil is so heavy that the well cannot be capped and the oil is only retained by hastily constructed dams which form reservoirs for the overflow oil. The well is located in Wiley canyon and is down 1400 feet with 6-inch casing.

The drill of an oil well that W. E. de Groot is sinking near West Lake Park this week penetrated a stratum of iron at a depth of 725 feet.

Madera.

In Swede gulch, near Coarse Gold, a large body of ore has been discovered in a prospect which is down about 35 feet. The vein of quartz is about 3 feet wide.

Nevada.

The Malakoff Co. is working the bedrock tunnel. The present small force of men may be increased.

Union: At the Cadmus mine work has begun extending the 320-foot level to reach a shoot which always paid well. The 10-stamp mill has been kept running steadily for the past two months on rock from the Home and Cadmus mines.——The new 10-stamp mill at the Texas mine is in full blast.

Placer.

The Red Dog mine at You Bet is running with a large crew.

The Hidden Treasure G. M. Co., at Centerville, has 135 men on the payroll.

The Three Stars quartz mine, at Ophir, has three vertical shafts, the greatest depth reached being 700 feet. Forty-five men are employed.

The Eureka Consolidated Drift M. Co. has found gravel in the shaft they were sinking, so much water was encountered that a drift is now being run to tap the channel below the shaft.

The Big Pine mine at Auburn is being operated by Bouk & Bushnell of Santa Cruz. In the lower drift they ran through a pay chute of 40 feet, with ledge from 2 to 4 feet thick, from which they netted about $2000. At the last crushing the rock went $10 per ton, sulphurets $100.

The Gold Ring mine, near Gold Run, has been sold to the Blue Gravel M. & M. Co. of San Francisco. An incorporation has been formed with a capital of $40,000 to prospect and work the mine. E. A. Moody has been appointed Supt.

A second party of experienced hydraulic miners has left Dutch Flat for Boise, Idaho.

A miner charged with having taken gold from the Big Dipper drift mine near Iowa Hill has been held to answer with bonds fixed at $1000.

Near Michigan Bluff, W. Stuart, Supt. of the American Bar quartz mine, is working fifteen men.

In the Eureka Con. drift mine on the Forest Hill divide, three miles north of Sunny South, Cal., the channel, for which search has so long been made under the direction of F. Chappellet Jr., Supt., has been found 300 feet above the main tunnel and 2100 feet from its mouth. This means much for drift mining in that section of California, and will doubtless result in the opening of a new and great mine and the employment this season of 200 men.

The Big Dipper Co. near Iowa Hill expects to have the mill running in ten days.

H Stemple is running gravel at the Pioneer below Yankee Jims.

The Gold Run M. & M. Co. near Gold Run has run its tunnel 1000 feet from a point on the bedrock beneath the first bench near Canyon Creek.

The mines at Gold Run and Dutch Flat that are now in operation are located on the deep Blue Lead.

The Dutch Flat Blue Lead Co. recently incorporated owns the ground under Dutch Flat and thence west to Bear river. A tunnel is being run under the management of S. Jordan toward Bear river.

The mining property at Green Valley formerly known as the "Gold Ring" is incorporated under the name of the Blue Gravel M. & Co. The new 10-stamp mill has been started.

The Pioneer mine, near Damascus, has issued its statement for January as follows:

	1899.	1898.
Value of gold bars	$10,466	$8,354
Total expenses	4 531	5,127
Net income	5,935	3,117
Tons of rock crushed	950	721

A ditch is being opened from Centerville to Sunny South to increase the water supply for the generator plant an the Hidden Treasure mine at Sunny South.

At the Mayflower mine near Forest Hill the company is compelled to run their machinery by steam on account of the scarcity of water.

The Dutch Flat Blue Lead M. Co. has been formed in Sacramento to operate a mine near Dutch Flat.

At Alta the gravel mines are working steadily.

Republican-Argus: At the Bellvue mine, Ophir, work is continuing. Eight men are employed. The last cleanup from the milling rock ran about $38 per ton.——The Crandall mine, three miles from Auburn, will have a 5-stamp mill working Monday next. Provision has been made for five additional stamps. The tunnel is in 500 feet on the ledge. The mine is owned by W. A. Freeman, B. F. Hartley, Gov. Clough of Minnesota and others.

Plumas.

Mrs. Gruss is adding ten stamps to the mill on the Genesee M. Co.'s property in Genesee valley.

Mr. Summers has bonded the McGill & Standart and Johnny Bull mining properties and will prospect and work them.

The mine and mill of the Jamison M. Co., near Johnsville, are again being operated.

Riverside.

The Gold Canyon M. Co. near Salton has recently built a wagon road and will build a track 400 feet long to the foot of a tramway now being constructed. The ore at the mine is ready for stoping.

The new Mountain Beauty district is located in the foothills of the Chihuachon mountains. This spur forms the southernmost end of the San Jacinto mountain range, and is on the line of Riverside and San Diego counties. The district resembles that of Mesa Grande in San Diego county.

San Diego.

At the Stonewall mine R. Strauss is superintending the cyanide process. Eighteen men are at work. The stamp mill is crushing low-grade ore. Water for the mill is taken from the mine shaft. The tanks are completed and will soon be in operation. There are several thousand tons of tailings which will be treated by this plant.

The Ranchita mine, near Banner, is reported sold to the Colorado & California M. & D. Co. for a large sum.

Santa Barbara.

An experimental oil well is to be driven near Lompoc on the McKay ranch. It is said surface indications justify the expense of such experiment.

Press: Interest is centered in oil development and some contracts are being made to drill in new territory. E. Daily has leased two acres on the beach on his Rincon Hill property at Carpinteria to J. R. Heath, who will soon begin operations. The Rincon mountains show indications, asphaltum and oil springs showing up in various places.——The well on Dr. Hill's place at Rincon point is down through the second oil strata and going deeper.——The Pacific Whaling Co.'s well back of Shepard's is down 1100 feet and the tools are stuck. Some oil was encountered but not enough to justify stopping. As soon as the tools are out the well will be pushed on down. The first well was down 1900 feet but found no oil.

Shasta.

A quicksilver prospect has been discovered at the head of Clover creek. Last summer Sisk & Bryan located a ledge of porphyry and iron ore. On the south side of the iron is 10 feet of shale. A prospect was followed on an incline towards the shale to a vertical depth of 14 feet, where there is 1 foot of cinnabar.

At Delta the mill is to be moved from the Laconia to the Butler mine.

At Keswick 1000 men are on the payroll of the Mountain Copper Co., 600 about the smelters and 400 at the mine.

At Kennett twenty-two men are employed in the Uncle Sam mine.

At the Uncle Sam mine near Kennett the mine is being retimbered. Twenty men are employed and ten of the forty stamps are in operation.

J. Salee, the owner of the Copper City properties, reported about to pass into the hands of a syndicate, tells the *Searchlight* that the sale is off and the property is not now under bond to anyone. With good roads and a continuance of fair weather he would begin hauling the ore down and shipping it to the smelters.

Twenty-two men are developing the copper property recently bonded by the Lewishon Bros. for $130,000.

Sixty-four mining claims were located one day last week on Backbone creek, near Kennet, on the Southern Pacific, twelve miles north of Keswick. This was occasioned by the bonding of the Golinsky group of copper mines for $130,000 to New York men, who have twenty-five men at work. With the establishment of smelters there, a demand for quartz for fluxing purposes would be created.

A rich strike of free-gold ore is reported from North Cow creek by three prospectors—Dale, Moore and Silence—who took out $1000 apiece in three days. The discoverers had their gold reduced to a brick in the sampling works at Redding and shipped a $3757 brick to the San Francisco mint. The ore is contained in an 8-inch vein and the rock is wired with strings and sheets of gold. The men were washing gravel in the creek bed, encountering coarse gold and several specimens that had evidently come from a quartz seam. The water got low and they prospected for the vein. They found a trace and followed it into the hill, making an open cut. The seam rapidly widened out to 8 inches.

Siskiyou.

At the Best Chance mine on Yreka creek Supt. Austin has the old shaft pumped out and is hoisting pay gravel.

At the Commodore mine on Barkhouse creek the lower tunnel is being extended to crosscut the ledge. It is now in about 400 feet and another month's work will probably be required to reach the ore. Stoping is going on in the upper level. Thirty men are employed.

W. C. Stanley, Supt. Jillson mine, reports the February clean-up the largest in its history. The monthly payroll is $3500, there being about thirty men employed.

The first clean-up from the placer mine owned by Mr. Hutchinson on the Klamath amounts to $7000 and represents a short run with a No. 2 giant. The mine is located thirty miles below Happy Camp.

In the Blue Gravel mine, near Yreka, last week a cave imprisoned four miners who made their escape through an old unused shaft.

The *Journal* says the Sheba mine at Patterson creek is attracting attention. Shares held at 80 cents on first discovery have jumped to $5.——F. Beaudry will extensively operate in placer mining at Wild Cat on the south fork of Scott river.——The Little Wonder mine at Cherry Creek is turning out rich ore.——Hornbrook reports the lack of storms makes the outlook dark for this year's mining and farming. The only class rejoicing is the river miner. It will be another good season for wingdamming.

Trinity.

The discovery of sylvanite ore near Coffee creek is announced by G. L. Carr, who owns a number of claims in that district.

From the Golden Jubilee mine ore has been extracted worth over $1000 a ton, much of it having been shipped to Selby.

The Forget-Me-Not has ore running $1382.

Tuolumne.

(Special Correspondence).—The shaft of the Golden Crown M. Co. at the Big Betsy is now down 325 feet, the vein still showing favorably. It is understood here that the San Jose officers have advanced the price of the stock to $2.50 per share.

Groveland, March 1st, '99.

The Bown mill near Robinson's Ferry is nearly completed and the new hoist will be put in as quickly as possible. The shaft is about 500 feet deep.

At the Mazeppa mine the shaft is down 90 feet.

The new 20-stamp mill at the Bown mine, near Tuttletown, is expected to start up April 1st.

The Tarantula G. M. Co., Ltd., has incorporated at Sonora. The registered office of the company is in England; capital stock, £130,000.

The Leap Year Gravel M. Co. has incorporated at Sonora. C. J. Berry of Selma, C. L. Waters of Fresno, G. Eager of Carters, C. B. Hawley and F. M. Cook of Sonora are directors; capital stock, $35,000.

The pump at the Genevieve mine, near Soulsbyville, is operated by compressed air furnished by the Black Oak compressor, 4000 feet distant, through a 2-inch pipe line.

At the Santa Ysabel, near Stent, No. 1 shaft has been sunk to the 600 level, where the ore body will be opened. Work has been progressing on the 400 level, and at the 500 level the ore body has been opened 75 feet.

Union-Democrat: The 10-stamp mill on the Mammoth will crush ore from the Republican of Jacksonville. The hoist on the latter is operated by compressed air transmitted by pipe from the Mammoth mill.——At the Shawmut-Eagle sinking and general underground work is being done. The mill is running ten stamps by steam power, and water is used for the compressors.——The Grizzly shaft is 450 feet deep, at which point sinking was discontinued and crosscutting begun.——The Black Oak mine, near Soulsbyville, is 750 feet deep; is equipped throughout with steam and water plants, has two large air compressors, a 30-stamp mill, two complete cyanide plants (percolation and agitation), and 6000 square feet of canvas tables. It has both milling and shipping ore, and is equipped with electric lights.——It is reported the vein in the North Fork mine near Arrastraville, which was lost by a fault, has been rediscovered by the present operators.——Sinking in the Confidence shaft at Confidence has been discontinued.——The Mazeppa shaft, near Stent, is down 190 feet, where the vein is said to be 18 feet wide.——The Vine Spring mine, near Columbia, is being reopened after a long idleness.——The force on the North Star and Black

Warrior, on Moccasin creek, is to be increased.

Ventura.

The tract of land in Ventura county set aside as a forest reservation by the President, consists of 60,000 acres at the head of Trabuco canyon.

Yuba.

Marysville *Democrat*: The surveyors under direction of the U. S. Debris Commission are at work on the north side of the Yuba channel, in the vicinity of the Hall farm, where they are stopping at present. There are now four men in the party at that point, and one, H. Vischer, who is stopping in this city. The survey is under the direction of the latter gentleman, who is preparing plans for work in river betterment.

COLORADO.

Mining Investor: The books of the surveyor of customs show that for '98 there were imported into the port of Denver, from British Columbia and Mexico, 18,865,125 pounds of silver-lead ore valued at $214,502. About the same amount of refined lead was exported to England and France, via the port of Galveston. During '97 this custom house received from British Columbia and Mexico silver-lead ore to the extent of 20,000,000 pounds, valued at $300,000. In the last four months of '98 the lead importations fell off on account of a rise in railroad rates of transportation, and an increased supply of lead-silver ores from the Colorado, Idaho and Utah mines, now almost equal to the smelter demand.

BOULDER COUNTY.

Miner: The Newmarket leasers have sent three carloads of ore to Denver from the Puzzler, and the Ward-Rose leasers one carload. ——The Emancipation mine at Sunshine is producing steadily. The mine is now 470 feet deep and 50 feet is to be sunk at once. The mine employs twenty-six men.——On the 200 east level of the Ward-Rose mine a 6-inch streak of solid ore, rich in gold, has been found.——The B. & M. mine has opened a new body of ore in the east 500 level, 155 feet from the shaft. There are 18 inches of solid iron. In the west 600 level the ore body is from 3 to 5 feet wide.

CHAFFEE COUNTY.

Coarse gold has been found in Cat gulch below Turret. The claim has been sold and the purchasers will commence sinking.

CLEAR CREEK COUNTY.

The Knickerbocker tunnel has cut a good body of ore at the distance of 1300 feet from the mouth.

A rich strike is reported in the Mary Ellen mine near Silver Plume. There is a 3-inch streak of ore assaying 22 ounces gold and 275 ounces silver per ton.

The Corry City mine has a chimney of ore from which have been taken twelve tons a month for eight months that averages 500 ounces silver a ton.

J. Robenson, Supt. Pelican and Dives mines, and C. K. Wolfe, Mgr. Chamberlain sampler, have bought a controlling interest in the Stevens mine on McCleelan mountain.

EL PASO COUNTY.

The Victor tunnel has a vein of 6 feet of gold sulphides and peacock copper.

The Creston Leasing Co. at Cripple Creek report net proceeds for January $30,000.

A strike has been made on the Coriolanus on Battle mountain, Cripple Creek, which returns values of something like 140 ounces to the ton.

Goodall, Kinsella & Chatfield of the Hawkeye lease, on the Wisconsin group, near Victor, have made a shipment of sixteen tons of ore, divided into three grades, giving returns of $32, $47 and $155 to the ton.

The Atlanta shaft at Victor will be sunk 100 feet to the 400-foot point. Work has been commenced. Attention has been given to breaking ore in the first level. The veins cut in the shaft will not be exploited for the present.

At the Red Umbrella in Eclipse gulch near Victor there is now in the bottom of the shaft 6 inches of ore, the average of which is said to be seven ounces to the ton. A contract has been let for sinking the shaft 100 feet.

A strike is reported having been made on the Hiawatha on Beacon Hill, Cripple Creek.

Mining Record: Lessees Reardon, Sims and Hight, working on the Kimberly at Cripple Creek have made a phenomenal find. After a round of shots had been fired, two miners went down to see the result and picked up some thirty pounds of almost pure sylvanite, one chunk that would weigh fifteen pounds was entirely metal. Alongside of this high-grade seam is 15 inches of ore that will assay well.

FREMONT COUNTY.

Dawson City has made its first sale, a one-third interest in a claim in Jennings gulch changing hands for $1000.

GILPIN COUNTY.

The Fish group of mines in Pine Creek district has cut 17 feet of ore that has a gold value of $20 to the ton.

GUNNISON COUNTY.

(Special Correspondence).—A sale has just been closed on the Bull-Domingo group of three claims by Haynes, Parrault & McManus to S. I. Hallet of Aspen, Colo. Consideration, $50,000; $5000 cash was paid on contract.

R. L. Hammill, who has charge of the Luck Strike, has bought a half interest in the Little Jessie group, comprising five claims.

A contract is to be let for sinking the main shaft of the Gunnison mine another 100 feet. The mine is equipped with hoist and is now 150 feet deep. The vein is 20 feet wide at the 150 station and the ore will average over $20 per ton.

Gunnison, Colo., Feb. 20th, '99.

(Special Correspondence).—The Vulcan mine near Gunnison is reported to have 3 feet of rich ore on the lower levels.

The Good Hope mine near the Vulcan ships several cars of ore monthly. Fourteen men are employed.

The contract to sink another 100 feet on the Gunnison mine has been let and work will commence at once.

The Midland mine near Gunnison is shut down for the winter. It is stated on good authority that there is 18 feet of ore in the bottom of the shaft.

A bond and lease have been secured on the Belle Flora near Gunnison by Cunan and others for one year at $10,000. The property has at one time produced some good ores, which were milled at a 10-stamp mill on the ground. The property is in bad condition and a new shaft will likely be put down, there being 3 to 6 feet of milling ore.

The Western Federation has just perfected an organization at Vulcan. Mr. Davidson of the Vulcan mine is not a union man and as a consequence he has discharged fifteen men already, and others will follow. The wages at the Vulcan are $3 for 10-hour day shift and the same for 9-hour night shift for miners and $2.50 per shift for trammers.

Gunnison, Feb. 25th, '99.

LAKE COUNTY.

A discovery has recently been made in the Horseshoe district, just over the Mosquito range from the head of Iowa gulch, where a body of lead carbonate and galena ore was found. The ground on which the discovery was made is owned by the Hilda M. Co., of which Messrs. Kountze & Sheedy are in control, and is under a lease to Messrs. Wuensch & Root of Denver.

The Hibernia mine of Leadville has opened an ore body that runs thirty-four ounces of silver and 45% iron excess.

Leadville *Miner*: The smelter trust that is now forming seems to be a certainty. Lessees and mine owners don't look upon it as being of any advantage to them. The Guggenheim smelter interests did not enter the former combine and will not enter this one.——The New Jersey Zinc Co., a concern that has unlimited capital and owners of the large zinc works at Mineral Point, Wis., who recently purchased the Colonel Sellers mine here for $50,000, had 500 tons of dump ore from the mine shipped to their works for a test run. The increase in the price of zinc spelter should stimulate this industry, but Leadville ores are said to contain too much iron to make practical separation.——Other smelting propositions are known to be under way here. Ward, Colo., smelting people are anxious to get a lease on the Elgin smelter here to run a pyritic plant. Operators are also negotiating for a lease on the Harrison Reduction Works, at the foot of Harrison avenue, owned by the National Lead Co. of New York. The owners of these works are anxious to get them off their hands, as the expense and taxes are quite an item. The works would have to be improved to make a modern smelter. They are also badly hampered for dump room.

MINERAL COUNTY.

A body of high-grade lead ore has been encountered in the Ridge claim at Creede.

Creede has added the Alpha and Kentucky Belle mines to her list of shippers. The Yellow Jacket and Corsair will soon follow.

Creede shipped 2565 tons of ore last week.

The Iowa tunnel, on Mammoth mountain, near Creede, is now in 160 feet. It will require 140 feet of work to reach the vein, which will give a depth of about 300 feet.

The Creede Co-operative mine is regularly shipping three to four cars a day to the smelter. Several hundred tons of concentrating ore are stored to await the starting of the concentrator.

OURAY COUNTY.

A rich strike is reported in the Atlas mine near Ouray. A reduction plant is to be built.

PITKIN COUNTY.

(Special Correspondence).—It is reported that a 6-foot vein of gray copper has been discovered in the Citizen mine at Pitkin. It joins the Maid of Athens.

Pitkin, Feb. 23rd, '99.

SAN MIGUEL COUNTY.

At Telluride it is rumored that the Smuggler-Union group of mines has been sold to the Calumet & Hecla people of Michigan for a consideration ranging from $1,500,000 to $2,000,000. No papers relative to the purchase have been filed in the county recorder's office. It is said that the new owners will work the properties on an extensive scale and that improvements will be made. "The force employed in the mines will be increased by 400 or 500 men, and the big mill at Pandora, one and one-half miles above Telluride, greatly enlarged." The report is unconfirmed.

The company owning the Little Mary and Euclid Avenue mines, near Telluride, will build a mill this spring.

Many residents of Telluride are going to new copper discoveries near that town.

The Pennsylvania tunnel, being run to cut the Smuggler-Union vein at a great depth, on the line of which are numerous veins, has reached a depth of 1300 feet and met a flow of water estimated at 145,000 gallons in twenty-four hours, being the property of the Smuggler-Union Co., and cannot be appropriated until after it leaves their mill and is discharged into the river.

Near Telluride the Bessie mill is crushing Montezuma ore, on which the last cleanup of the plates gave a return of $12.50 to the ton. The Montezuma vein is gaining in extent with the drift.

The Liberty Bell mill in Telluride district has resumed. Through experimental stages the mill has been perfected until it is in shape to save a satisfactory per cent of the values of the ore.

Four cars of ore have recently been shipped from Ophir district—one from the Alta, one from the Silver Bell and two from the Carribeau.

IDAHO.

The Big Buffalo mine in the Buffalo Hump country near Grangeville, which was sold a short time ago to Toronto and Eastern parties, is described as a solid ridge of quartz standing 25 feet above the surface and 40 feet wide.

Fourteen men are at work on the Peacock mine in Seven Devils district. Two hundred feet of tunnel are completed and ore in sight.

The Buffalo Hump Development Co. has concluded the purchase of the remaining two-thirds of the Gem City claim in the Buffalo Hump camp, near Grangeville.

The Decora and Blue Jacket are working fifteen men.

C. H. Gilbreath is in Portland forming a company to place a dredge on 1000 acres he controls above Huntington near Old's Ferry. The mean depth of the gravel is 12 feet to bedrock and colors are found all the way from the grass roots down. The dredge will begin operations in the river and cut a channel 12 feet wide.

At Florence, the Florence Gold Dredging Co. is capitalized at $500,000 to operate this summer. R. G. Wood is secretary. The company will dredge in that vicinity. The company owns about 400 acres of placer ground. The prospecting already done shows the value to be 19 cents per yard; the proposed dredge has a capacity of 5000 yards per twenty-four hours.

The Poorman Co., at Silver City, has reduced its force of miners, and will try contracting.

It is said the Crackerjack mine, in the Buffalo Hump district, has a streak of quartz 10 inches wide which assays $2457.61 per ton.

In the south drift of the Trade Dollar mine at Silver City ore is being sacked that is streaked with gold. The ore is from 4 to 16 inches thick, the vein being from 2 to 4 feet thick.

In the Buffalo Hump country there are fifty men developing their own claims.

The De Lamar Co. at De Lamar is building a dyke of gunny sacks filled with sand placed along the side of the tailings dump to prevent the spring floods from washing it away.

In the Hiyu mine, near Florence, 2½ feet of solid ore has been encountered in the shaft at a depth of between 70 and 80 feet below the first level. The shaft is going down at the rate of a set of timbers for every two shifts. The work of sinking will continue to the depth of 200 feet below the first level.

The Florence Dredging Co., a corporation, has been organized to work placer mines at Florence by means of the New Zealand endless bucket system.

The Lucky Boy at Custer is reported to have made another strike. From two stations on the 700-foot level running west crosscuts have broken into ore and 15 feet is now exposed that is said to average $25 in gold and thirty ounces silver. In addition to this samples of ore were found that show native silver and free gold.

Libby *News*: The Bunker Hill & Sullivan tunnel, at Wardner, connecting the mine with the mill, is being driven 325 feet monthly. It is in 4000 feet with 6000 feet to go before completion. The 9-inch main from the compressor to the mine is two miles long and goes over a mountain. It will be laid in the tunnel when the latter is completed.——The mines at Wallace, Wardner and Mullan are mining 100,000 tons of ore per month, which is concentrated to 18,000 tons before shipping. The mines which produce this are the Bunker Hill & Sullivan and Last Chance at Wardner; the Tiger & Poorman, Helena & Frisco, Standard, Mammoth, Black Bear and Hecla near Wallace and the Morning at Mullan.——The Old Abe at Wardner is being developed by a 1500-foot crosscut tunnel. Bodies of silver-lead ores have been encountered, as well as streaks of copper glance. Its ore is chalcopyrite. This property belongs to J. Finch and St. Clair Bros. of Wardner, who will put in a compressor in the spring.

MONTANA.

It is expected that the Boston & Montana Co. will soon reach the $10,000,000 dividend mark. A regular dividend of $1 per share, paid Feb 20, brought the total dividend disbursements of this company up to $9,875,000. At the present price of copper it is calculated that the company will pay $24 per share this year. In '98 the company paid $16 and expended a large sum in improvements.

The First Shot mine at Basin has shipped its first carload of ore.

The crosscut from the shaft to the vein at the 600-foot level in the Hope mine in Basin is now in about 20 feet. Thirty feet more will bring it to the lead.

A report from the Wright & Edwards mine at Barker says a body of ore has been discovered in a crosscut at the 300 level.

The Sunbeam mine near Sheridan has been sold to J. H. Pankey.

The Chicago M. & D. Co. will operate a large dredge near Conrey, at the mouth of Alder gulch, the coming season. The dredge has the endless bucket system, moving at the rate of eighteen buckets per minute.

The annual report for '98 of the Hecla Con. M. Co. of Glendale shows shipments for the year as follows: Cars bullion, 40; cars matte, 9; cars ore, 3; total value, $273,687.85.

In the Parrot mine, at Butte, a strike has been made in which 11 feet of ore are exposed.

Messrs. Smith & Easton have commenced work in the Mystery tunnel, near Phillipsburg, formerly the property of the Phillipsbury M. & M. Co. Several hundred feet of tunnel have been driven into the mountain and some good ore has been found. The largest lead that has been cut is about 18 inches wide and the ore will average about forty ounces in silver, but it is base and must be shipped to Butte or other smelters for treatment.

A shipment of high-grade ore from the Levi Burr mine, at Hasmark, was recently made by T. E. Mitchell, lessee. A tunnel about 200 feet long has been driven on the lead and work is now in progress to connect the same with the shaft. The last car of ore was taken from the shaft.

NEVADA.

Supt. Ross, who has charge of the Comstock pumping, wired from Virginia last Thursday as follows: "The water has been lowered to 50 feet below the 1750-foot level, or 77 feet below the Sutro tunnel discharge. Several stops were made during the past twenty-four hours on account of shaft work. The water is still going down." After it goes down a few feet more the work of lowering the water must temporarily cease till the old pump rod, pipe, etc., are got out of the way, when unwatering will be resumed. Mgr. Ross made the following statement of the result of the Risdon pump Feb. 27th: "During the past week the Risdon pumping plant was tested under light pressure and every part of the system found in perfect order, from the connection with the Water Co.'s flume to the valves of the 1750 level. The pump or elevator was started under full head on Feb. 20th, and kept running until Feb. 25th, when a defective pipe in the discharge column gave way and the pump was stopped and lifted to the 1750 level. A duplicate pipe that the Risdon Co. had on hand will be substituted for the defective pipe. The pump will again be lowered and started after having made such changes in the working parts as the first work indicated as being necessary.

"During the operation of the pump water was lowered 53 feet below the 1750 station and elevated 28 feet above the station to the drain box leading to the Sutro tunnel, making a total lift of 81 feet.

"Quantity of water used ranged from 40 to 95 miners' inches and the quantity discharged has ranged from 3000 to 6000 gallons per minute; this includes the pressure of water. No attempt has been made to get at efficiency as the Risdon people regard their start as largely experimental. They made several changes in their original plans to accommodate the capacity of the Sutro tunnel drain boxes and have not stated what quantity of water they expect to pump at the start. A considerable area of ground has been drained as on our first stop of two hours the water rose over 17 feet. Since that time the water has raised in the shaft very slow during the stops and is now raising slowly. For and on account of the Savage M. Co. we are cleaning out the connecting drift with the main Sutro tunnel for the purpose of catching up and conveying such water as there is now flowing to the lower levels into the drain tunnel boxes. The water in the Combination shaft stands at a point 46 feet 8 inches below the station on the level of the connecting drift with the Sutro tunnel. We have continued the removal of rock and timbers at the connection of the Osbiston shaft with the Sutro tunnel for account of Gould & Curry and Best & Belcher Companies."

Work will be resumed in the Eureka Con. mine, Eureka. The company has let a contract to run a drift on the eighth level, to explore some new and promising ground. The Eureka Con. has paid $5,112,500 in dividends to date and levied $585,000 in assessments. The last dividend was paid Jan. 5th, '92, at 25 cents per share. The last assessment was Aug. 4th, '98, of 20 cents per share.

The Golconda smelting works employ about ninety men.

The April Fool mine in De Lamar district, Lincoln county, is producing twenty-five tons of high-grade ore daily.

In the Poorman mine, near Pioche, men are at work taking out galena. The Alps mine will again be started up.

Active work is in progress, under the direction of F. Mitchell, at New Pass, sixteen miles west of Austin, near Silver Peak. Developments thus far have been gratifying. The Gold Belt has been opened up through three different avenues, and shows ore running from $12 to $18 in gold per ton.

The Magnolia, at DeLamar, has shipped two carloads of ore to the Germania smelter at Salt Lake, Utah.

The Grand Prize and Buckeye mines at Tuscarora have been bonded by Holmes and Knox of Salt Lake City and R. R. Bowles of Denver. Electric energy from the Owyhee river, transmitted fifteen miles, is talked of.

Elko *Independent*. Good finds have been made in the old Delker district in Butte valley. Copper ore valued at $50 per ton and ore assaying $14.50 in gold have been found. There is a body of copper ore in the Emma. The district was prospected nine years ago and abandoned. Recent workings show bodies of ore carrying both gold and copper. A number of new locations have been made.

NEW MEXICO.

The Old Abe mine near White Oaks has been equipped with a cyanide plant with fifty tons daily capacity.

There are forty men leasing on the second and third levels of the Snake mine near Hillsboro, and making good wages.

John A. Kruse, a Chicago mining man, has purchased the Prosper mine; consideration, $10,000, one-half down.

From Jan. 1st to Feb. 23d, '99, the mines of Hillsboro produced 2315 tons of ore.

At Hillsboro there are seventy-eight men employed on the Richmond. The Trippe has increased its force to eighty men.

Two of the mines of the Golden Era group give employment to fifty-five lessees.

In the Mastodon mine, near Hillsboro, about 30 feet west of the old workings, a new strike is reported. The vein is 1 foot wide and assays $70 gold and $20 copper to the ton.

Keller & Galles have bought the American mine for $11,000. This property is the western extension of the Bonanza.

A discovery has been made in sinking the Blue Bandana shaft on the extension of the Red Bandana lode, near Elizabethtown. This shaft is 350 feet east of the point where the working tunnel of the Red Bandana cuts that lead. The Red Bandana has been opened up for 700 feet west. The new shaft is on a direct line with the lead. The object of sinking the shaft was to reach bedrock and then drift for the lead. The shaft is now 280 feet deep. At

70 feet it was discovered that they had truck placer ground.

The Silver City Reduction Co. has contracted with Mr. Chapin of Crittenden, rizona, for a minimum delivery of twenty ons of copper pyrites ore per day for one

At Chloride Flat fifteen miners are employed in the old mines three miles from Silver City. The ore produced is an iron-lead which averages about forty ounces silver.

OREGON.

On Deep creek, G. Snodderly has his placer ine, near Susanville, opened and is ready to tart his hydraulic when the water starts.

Smyers & Wasson are arranging to operate he Smyer placer mine on Deep creek, and a ydraulic on Quartz gulch.

The Urie Dredger Co., operating below the own of John Day, have prospected to the iver bars below Susanville.

The mill of the Badger Co., near Susanville, hich was shut down during the cold eather, is again in operation reducing ore rom the Badger mine, with the usual force f men at work.

At the E. & E. mine, Bourne, the Baker City *Republican* says trouble exists because f no regular payday since Nov. 1st, '98, attachments being levied and threats made by ome of the employes. Mgr. Searles was in San Francisco last week to get money to meet urrent obligations.

UTAH.

A new gold find is reported from the range ast of Minersville. Ore assaying $3000 per on is said to have been found.

A copper strike is reported from Beaver ake in the Beaver Lake Copper M. Co.'s roperty.

The East Dip G. M. Co. of Camp Floyd district has filed articles of incorporation. The ompany owns the Cortado Lode, Cortado ode No. 2, Cortado Lode No. 3 and the Corado Wedge, which are valued at $35,000.

The South Daisy M. Co. of West Dip, Camp loyd district will build a mill.

Rich copper prospects are reported from the egion south of Castledale. A district will be ormed embracing Cedar mountain country.

It is reported that the Markham mine at ingham has been sold to the Red Wing Co. or $40,000.

The Galena mine at Fish Springs is shipping ead-silver ore regularly to the Salt Lake melters.

The Eureka Hill mill, at Eureka, after running continuously for four years on 200 tons of ore a day, has been closed down for repairs.

The Boss Tweed of Tintic has shipped two carloads of high-grade ore to the sampler.

The Four Aces mine at Tintic has sent two carloads of ore from the galena streak in the property.

The Uncle Sam mine at Knightsville has shipped five carloads of ore to Salt Lake.

A cyanide plant is to be built at the Midas mine, Deep Creek.

The Utah Con. at Tintic will sink a 500-foot shaft on the property.

The Eureka Hill mine and mill at Eureka has been closed down and seventy persons let out of employment, it is said, temporarily.

The Daisy of West Dip reports work on four new tanks at the mill. Regular shipments of gold dust are being made.

C. Butters will join the Raven M. Co. of Chicago and will undertake the introduction of the company's product from the elaterite and asphaltum deposits in the Uintah reservation abroad.

The Juab County *Republican* says that the Bullion-Beck has now five times more ore in sight than its Hill neighbor ever had.

Tribune: The Ore Producers' Association will hold a meeting soon to consider the question of admitting ores from Canada into the United States free of duty.

Park *Record*: The final clean-up on the run of Ontario tailings at the Marsac mill is completed and the mill, leachers and refinery are closed. The mill was started on this run June 1st of last year.——The Anchor mine at Park City is to have a new mill in the spring.

Tribune: The Annie Laurie M. Co., whose ground joins the Martha Washington at Provo has let a contract to B. G. Milner to sink their shaft 100 feet. The shaft is now 100 feet deep.

Tribune: At the Midas mine, Deep Creek, a strike has been made in which the ores show a valuation ranging from $16 to $238 per ton. Four feet of ore has been exposed that averages $40 per ton.

WASHINGTON.

The Princess Maud ledge, at Republic, has been encountered in the tunnel at a depth of 284 feet, midway between the two shafts on the property.

According to a daily newspaper dispatch seventeen quartz claims in the glacier mining district, near Tacoma, owned by J. W. Knapp and associates of Buckley, are bonded to A. M. Hitchcock of Alameda county, Cal., for $250,000. The sum of $15,000 is paid down, $15,000 more is to be paid when possession is taken and the balance in 1900.

Fifteen new mining companies were organized in Spokane last week.

The Insurgent mine at Republic is reported to have a 16-foot vein.

A new strike is reported from the Flag Hill claim at Republic.

In the Summit claim at Republic a blind lead has been cut in a crosscut tunnel.

In the east drift on Lone Pine at Republic the ore body has been crosscut and shows 15 feet of ore. This discovery is within a few feet of the side line where the Insurgent fraction joins the east side of the Lone Pine.

In the Princess Maud ledge at Republic there is nearly 5 feet of quartz in sight and footwall is not reached.

A telegram received by J. B. Dabney, president of the Agnes G. M. Co., which is operating in Republic, from T. A. Helm, states that the vein on the Agnes mine at Republic had been encountered and opened to a width of 16 feet without reaching the wall.

Considerable prospecting is being done in the Lake Chelan district near Railroad Creek Camp.

WYOMING.

A group of copper mines near Sherman Hill, thirty-five miles west of Cheyenne, are reported sold to a Denver company for $40,000.

FOREIGN.

BRITISH COLUMBIA.

A strike of high-grade ore has been made on the Jewel claim, near Greenwood, owned by the Jewel Development Co., London. They have a 275-foot shaft, and in a crosscut have a 9-foot ledge, which goes high in gold and copper.

In the Velvet property, on Sophie mountain, near Rossland, the crosscut from the 160-foot level, 40 feet from the shaft, is in an ore body 6 feet wide.

The Gray Horse, near Nelson, has 14 inches of high-grade ore and 3 feet of ore of a lower grade.

The Gray Eagle mine, thirteen miles from Davenport, on Hawk creek, has ore which assays $129 to the ton silver and lead, and 18 inches of solid galena have been struck.

The Dundee mill, at Ymir, is daily crushing forty tons of ore. The management of the company asserts that it can treat ore averaging $7.50 to the ton.

In the Columbia and Kootenay property at Rossland a strike has been made in a winze on the 350-foot level, said to extend entirely across the winze.

The litigation in the Le Roi case has been settled out of court.

It is reported that a Scotch syndicate has bonded the St. Eugene group of mines at Moyie in East Kootenay for $400,000.

The Slocan Ore Purchasing Co. is looking for a site to build a sampling works at Nelson.

The Fontony mine at Camp McKinney has been sold to a Victoria, B. C., syndicate headed by James Dunsmuir. Machinery is to be put on the mine at once.

The Comstock mine near Silverton has commenced the season's shipments.

The Union Jack group at Ymir will commence shipping as soon as the snow melts.

At the Dundee mine at Ymir the main shaft is down 263 feet. Drifting on ore is being carried on at the 200 level, where it is 18 feet thick.

The Montana shaft at Ymir is sinking in a body of solid ore the full width of the shaft.

The shaft on the Evening Star at Ymir is now 75 feet deep.

Nelson expects the Slocan Ore Purchasing Co. to erect sampling works there.

Gold-bearing quartz has recently been discovered in the vicinity of Quesnelle.

An electric plant is being added to the Coxey at Rossland of 15 H. P.

The plant at the Velvet mine, Rossland, is being augmented by a 60 H. P. boiler and a large pump.

A 60 H. P. boiler is being added to the plant on the Green Mountain mine near Rossland.

In the Velvet at Rossland an ore body has been crosscut on the 100-foot level of shipping grade. This ore shoot is known to be 170 feet in length, 160 feet in depth and from 4 to 10 feet in width.

A strike has been made in the Kootenay Columbia near Rossland in the 350-foot level.

One hundred and forty tons of ore from the St. Eugene mine at Moyie has been shipped to the smelter at Trail. This is the first shipment from the St. Eugene.

Economist: The new working shaft on the Cariboo, in Camp McKinney, has reached the 300-level and drifting for the ledge is now in progress.

Commercial Paragraphs.

GEO. E. TRUAX, the Denver manufacturer of the Truax ore car, proposes to locate at 114 First St., San Francisco, there to continue its manufacture on a larger scale.

THE Electrical Engineering Co. has just moved into its new brick building, erected for its special use, at 509-511 Howard St., San Francisco, Cal. As in the past, this company will give particular attention to all electrical machinery pertaining to mines.

THE San Antonio Water Co. of Ontario, Cal., have recently purchased from the Machinery & Electrical Co. of Los Angeles, Cal., two Downie double-acting deep-well pumps, for the Twenty-first and Twenty-second St. wells in North Ontario. These pumps are reported to be the largest, heaviest and most expensive ever installed in southern California. The M. & E. people have just completed the installation of their No. 6 Wonder pump for the same company, the same to be used in the Sixteenth St. well in North Ontario. The Machinery & Electrical Co. have just received a new type of the Snow duplex sinking pump, Renshaw's patent. They have also added a line of heavy-pressure pumps for mine use. The San Antonio Water Co. of Ontario have purchased of them a strong developing outfit, to be used in sinking new wells.

Recently Declared Mining Dividends.

Mead G. M. & M. Co., S. F., 10%; payable March 2.

Boston & California G. M. & M. Co., 1½%; payable March 2.

Bunker Hill & Sullivan M. & C. Co., Idaho, $21,000; payable March 4.

Calumet & Hecla, Michigan, $10 a share and $30 extra; payable March 23; with the $40 thus declared, the 110th dividend declared by the company, the total dividend disbursements aggregate $59,850,000. This is the fourth for the fiscal year, beginning May 1, and makes $70 thus far declared, as against $40 last year.

Industrial Notes.

—Stockton, Cal., wants the S. F. & S. J. V. R. R. shops located there.

—Great Northern surveyors are said to be working for a route to Republic.

—Southern California stockmen are looking for pasturage near Flagstaff, Ariz.

—A $50,000 pulp factory is to be built near Floriston, Cal., on the Truckee river.

—Modoc Co., Cal., owners are refusing 9 cents per pound, on foot, for beef cattle.

—The Sierra Valley Railroad is to be extended from Claireville to Mohawk Valley, Cal.—fifteen miles.

—Last month was the dryest February on record in California. The previous dryest February in that State was in '96, when .09 inches fell.

—The Humboldt river, Nevada, is now running bank full, enough water going to waste which, if stored in reservoirs, would irrigate millions of acres of land in the broad valley through which it flows.

—Supt. Dame of Tacoma, Wash., says that the Washington Power Transmission Co. has been incorporated under the laws of New Jersey, with a capital stock of $1,250,000, to develop electrical power at Cedar river.

—Building the railroad from Skaguay to the summit of White pass at an elevation of nearly 3000 feet is completed. The event was made the occasion for an exchange of courtesies between the railway and Canadian officials.

—The Utah, Nevada & Southern Railroad has filed articles of incorporation in Nevada to build a railroad from the Utah-Nevada State line southwest across Lincoln county, Nev., to Vanderbilt, Cal., to be an extension of the Utah & Pacific.

—The Salt River Valley & Globe Toll Road Co. has incorporated at Phœnix, Ariz. The road has the financial backing of the Black Warrior Copper M. Co. of Globe. By the projected route the distance from Phœnix to Globe will be ninety-three miles.

—The President has issued proclamations setting aside the following as forest reserves: The Trabuco canyon forest reserve in California, 109,920 acres; the Fish Lake forest reserve in Utah, 67,840 acres; and the Gallatin forest reserve in Montana, 40,330 acres.

—The 50-mile gap between Surf and Elwood, Cal., on the coast division of the Southern Pacific, is to be built, completing a new line from San Francisco to Los Angeles. A direct connecting line between Ventura and Santa Monica along the coast is also contemplated.

—At the Sacramento, Cal., railroad shops last Saturday was forged a walking beam for the steamer Piedmont, said to be the first work of the kind ever done west of Pittsburg. It is a diamond-shaped piece of framework of wrought and cast iron to avoid expansion from heat. With its equipments the beam weighs about twenty tons.

—A number of California capitalists have formed a company in Reno, Nev., and have incorporated under the laws of Nevada, taking the name of the Nevada-Sierra Oil Co. The object of the company is to engage in the operation of mines, lands, ditches, canals, pipe lines for oil and water; to distribute to cities and communities water, oil and power. The amount of capital stock in the company is $400,000.

—The manager of one of the meat markets at Dawson has reached the coast and is reported as saying: "At one time the retail price of the best beef was $1.50 per pound, and it was not at all plentiful then. For a year or more it remained at this high figure, but last winter the price began to fall, and it has been going down ever since. The wholesale price is from 15 to 25 cents per pound by the carcass and the retail price is from 20 to 50 cents per pound."

—The North Fork Ditch Co. of Auburn, Cal., proposes to supply Sacramento with water, to be carried in a covered cement pipe to Folsom; a filter plant to be erected there to clarify the water, then to be conveyed in a large steel pipe to the eastern boundary of Sacramento; a stand pipe to be put up there and from that the water flows into the mains; the city to pay about $40,000 per year interest on the amount of the $800,000 investment.

—It is locally asserted that the much-talked-of Port Angeles, Wash., steel and tin plate works will soon be an assured fact. Cronemyer of Pittsburg is reported investigating the Barclay sound iron mines. He has a 99-year lease on the Barclay sound properties on Vancouver island, forty-five miles north of Port Angeles. Under the terms of the lease work must commence on the iron mines before April 1st. Work is to begin at Port Angeles on the tin plate factory and steel rolling mills. It is estimated that it will take from $1,500,000 to $2,000,000 to start the industry.

—A new land district in Alaska is created by a proclamation signed by President McKinley, north of the Porcupine and Yukon rivers, except as to the latter river only, from its intersection with the sixty-sixth parallel and north of that parallel as it extends to the Bering sea and west of the 154th meridian. This leaves a strip 160 miles in length, extending from the Yukon to the Arctic ocean, which is still retained in the district of which Weare is the land office location. The United States Land Office will establish a new town, Peavy, located at the head of navigation on the Koyukuk river, about 800 miles from its junction with the Yukon.

—At Suisun, Cal., E. H. Winship of the Clear Lake Power Co. says that Cache creek of Lake county will furnish water power to generate electricity for light and power for Santa Rosa, Petaluma, St. Helena, Napa, Vallejo and Benicia. A diverting dam will guide the water into a flume 4x8 feet, following the contour of the mountains for five miles, the flume having a fall of five to the mile and an elevation of 262 feet above the creek bed at the terminus of the flume. The water is then to be conducted in three 40-inch pipes 950 feet to the turbines in the power-house, on the same shaft as the dynamos. From the power-house a pole line holding six wires, carrying 40,000 volts, will be constructed to Calistoga. At Calistoga the line divides, forming two circuits of three wires each.

—E. C. Hawkins, chief engineer White Pass & Yukon Railway, says that since the British Columbia alien mining law went into force, Skaguay and Juneau have been very dull, due to the exclusion of American miners from Atlin. The majority of the miners in that district are Americans. The exclusion act is driving the miners into Alaska from Atlin. Many are prospecting in various parts of the Northwest. His company will build the line through to Bennett, as they regard the Klondike as a permanent camp. There are now 1600 men at work on the road.

Personal.

W. J. ADAMS has returned to San Francisco.

S. DANA GREENE is the new Gen. Sales Mgr. General Electric Co.

W. C. RALSTON returns to California from New York this week.

O. S. GABBS of San Francisco is examining mines near Tucson, Arizona.

J. S. LAWSON is the new Supt. Deadwood & Detroit M. Co., Deadwood, S. D.

GEO. W. COOK resumes charge of the Garden City property at Leadville, Colo.

F. C. FENNER has been appointed Supt. Lowell & Arizona C. M. & S. Co., Bisbee, Ariz.

J. A. PANTING has been appointed Gen. Mgr. Burnt River G. M. & M. Co., Baker City, Or.

E. H. WEBSTER, Supt. Grand Central mine, Minas Prietas, Sonora, Mexico, has resigned.

G. T. RIVES, Supt. Golden Cache mine, has returned from San Francisco to Lillooett, B. C.

W. G. DODD and D. E. Bigelow of the Union Iron Works have returned from Randsburg, Cal.

W. S. WEBB, third Vice-Pres. New York Central, is at Los Angeles, Cal., with a party of thirty-five.

G. F. BEVERIDGE of San Francisco has taken hold of a mining property near Dolores, in the Sierra Madres, Sonora, Mexico.

O. A. VANDERCOOK has gone to the Sheep-trail mine, near Kingman, Ariz., to take charge of the mill at that place.

STIRLEY MAHON, formerly foreman Creston mine, Minas Prietas, Sonora, Mexico, is now foreman Yellow Aster mine, Randsburg, Cal.

W. H. BRADFORD, former Supt. La Grange mine, Trinity Co., Cal., is in Arizona with A. J. Otis of the Santa Ana M. Co., on an extensive prospecting expedition.

W. C. QUINBY, who has represented the MINING AND SCIENTIFIC PRESS in various parts of the earth, has returned from Australia and will shortly leave for the west coast of South America.

A. P. DAVIS of the United States Geological Survey, who made the original report on the Buttes reservoir and dam, is in Florence, Arizona, in charge of the work now in progress.

CHAS. BUTTERS of Oakland, Cal., has gone to New York City and will shortly leave for Europe for the purpose of introducing abroad the product of the elaterite and asphaltum mines of Utah, in which he is interested.

JOHN M. BECKWITH, formerly Supt. of the Silver King (Ltd.) mines of Calico, Cal., is now at Goongarrie, Western Australia, managing mines for an English company. As a result of promising development a 20-stamp mill is to be built.

THE following have been appointed trustees of the Colorado School of Mines: Frank Bulkely, Mgr. Ibex mines at Leadville; Dr. Paul, Mgr. Aspen mine, Aspen: W. S. Stratton, owner Independence mine at Victor, Colorado Springs; Col. E. L. Bertoud, Georgetown.

MAJOR F. A. CLARK of San Francisco has built a unique model of the Golden Gate mine, Tuolumne Co., Cal., a decided novelty in material, method and construction. It is built of blocked wood and admits of being readily taken apart at any level. Looking from the front it shows the footwall stripped, the various levels and all the stoping and pillars. The ground surface is a shell of wood cut to contours, with buildings and plant thereon in colors, the whole thing being accurately drawn to a scale, and constituting an admirable illustration of the actual workings of the mine.

A. MCDONALD, the Klondike millionaire, is in Glasgow, Scotland, where he is trying to float a company to develop his Klondike property. The McDonald's Bonanza, Ltd., is the name of the company that has been incorporated, with a capital of £450,000. It is the intention of the organization to acquire from McDonald & Ferguson the following claims in the Klondike: No. 2 above Discovery on Bonanza creek, and Nos. 1, 2, 3, 7 and 8 on Skookum gulch. The prospectus of the company states that in '97 gold to the value of $32,000 was taken from one of the claims, an average of $40 to the ton of gravel removed, and that another claim in '98 yielded $175,000, an average of $50 to the ton. The value of the gold deposits is estimated as follows: No. 2, above Bonanza, $4,500,000; Nos. 1, 2 and 8 on Skookum, $1,435,000, and Nos. 7 and 8 on Skookum, $785,000—a total of $6,720,000.

Obituary.

JNO. FRANCIS, Gen. Mgr. Tucson, Arizona, smelter, died of Bright's disease, Feb. 21st, aged 51.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey, Strong & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING FEBRUARY 21, 1899.

619,933.—STOVE POLISH—W. Q. Adams, Portland, Or.
619,934.—WOODEN PAVEMENT—J. Bucktel, Portland, Or.
620,084.—CANNED TOMALES—J. Burozl, S. F.
619,865.—WINDOW FLY ESCAPE—A. J. Collar, Yreka, Cal.
619,868—TELEPHONE APPARATUS—Cranston & William, S. F.
619,725.—HAY PRESS—J. Cruickshank, Woodland, Cal.
619,727.—GOLD COLLECTING APPARATUS—J. T. Davis, S F
619,728.—ARTIFICIAL FUEL—J. T. Davis, S. F.
619,720.—ARTIFICIAL FUEL—J. T. Davis, S. F.
619,876.—WATER HEATER—M. H. Dorgan, S. F.
619,958.—WIRE SCREEN—Hipolito & Mastin, Los Angeles, Cal.
619,964.—PIANO ACTION—F. W. Kringel, Los Angeles, Cal.
620,045.—FRUIT GRADER—Morley & Patrick, Salem, Or.
619,904.—SINGLETREE—W. P. Murphy, San Jose, Cal.
619,989.—CAR FENDER—V. Pfaff, S. F.
619,991—ANIMAL NOZZLE—J. R. Reynolds, Healdsburg, Cal.
619,841.—CAR FENDER—G. Richmuller, S. F.
619,996.—GOPHER TRAP—C. W. Roth, Piru City, Cal.
620,060.—BICYCLE GEAR—W. A. Tickner, Marshall, Wash.

NOTE.—Plain and Certified Copies of U. S. and Foreign patents obtained by Dewey, Strong&Co., by mail or telegraphic order. American and Foreign patents secured, and general patent business transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

WINDOW FLY ESCAPE.—A. J. Collar, Yreka, Cal. No. 619,865. Dated Feb. 21, 1899. This invention relates to a device and attachment for windows for the purpose of permitting and assisting the escape of flies from the interior of a room to the outside. It consists essentially in the novel construction of a horizontally disposed channel or channels formed in the bottom rail of the sash and beneath the glass, a smooth lining fitted therein and a shield and revolving roller contained in the shield having a periphery of light hair, fur or felt which contacts with the glass and assists in carrying the insects down into the channels beneath. It is the tendency of flies to move downward on the glass, and if there was no obstruction at the lower edge, they would escape beneath it, but the thickness of the sash offers such an obstruction, and this the present device avoids.

COIN CONTROLLED AND REGISTERING TELEPHONE APPARATUS.—Messrs. R. D. Cranston and S. M. Williams, San Francisco, Cal. No. 619,868. Dated Feb. 21, 1899. The object of this invention is to provide a coin-controlled registering apparatus which may be used in conjunction with any device where such an apparatus is applicable, and especially in connection with telephones. The apparatus comprises a normally locked mechanism and means whereby it is released by a current from the central station to open a circuit and a coin-controlled means for restoring a broken circuit after it had been broken by the central office so that the user may restore the telephone to a condition for use with the subscriber after the coin has been so inserted.

THE ROESSLER & HASSLACHER CHEMICAL CO.
100 William Street, New York.

CYANIDE

Peroxide of Sodium

Hyposulphite of Soda

Chloride of Lime

Sulphide of Iron

And other Chemicals for Mining Purposes.

QUARTZ SCREENS
A specialty. Round, slot or burred slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American planished Iron, Zinc. Copper or Brass Screens for all purposes. CALIFORNIA PERFORATING SCREEN CO., 146 and 147 Beale St. S. F.

I. L. Burton Machine Works.
PATENT CENTRIFUGAL, TABER ROTARY, COLUMBUS STEAM..... Pumps.
Highest Efficiency, Simplicity and Durability.
Petterson Current Motor for streams not less than 3-mile current. Horse Powers, Portable Wood Saws. Some second-hand Pumps and Gas Engines. Steam Engines and Boilers for sale cheap. 115 and 117 First Street, San Francisco, Cal.

POSITION WANTED by experienced cyanide man as superintendent of a mill or as assayer and chemist. Technical graduate. Will take charge of a cyanide proposition for a small salary with a percentage of the profits. Address S. C. M., care of Mining and Scientific Press. San Francisco, Cal.

WANTED.—Millman thoroughly understanding concentrating and amalgamating by stamps or Huntingtons, all latest methods known, desires position at an early date with some reliable company in U. S. or out. Best of references furnished. Address K. W. A., this office.

WANTED—Position by a Mining Engineer, Assayer and U. S. Mineral Surveyor.
Speaks Spanish fluently. Best of references. Address P. C., this office.

WANTED—SITUATION BY A PRACTICAL MILLMAN AND ASSAYER.
Would go anywhere. Best of reference. Address F. B., care of Mining and Scientific Press.

WANTED—POSITION BY A CHEMIST, ASSAYER and MINING ENGINEER.
Cyanide a specialty. Speaks Spanish. First-class references. Address Box 28, this office.

WANTED—ASSAYER AND ANALYST DESIRES POSITION.
Experienced and reliable. Excellent references. Address COMPETENT, care of Mining and Scientific Press.

WANTED TO BUY—AN ASSAY OFFICE OR CHEMICAL LABORATORY, or would purchase an interest therein. Experienced in all branches of inorganic and organic analyses. References exchanged. Address Chemist, this office.

WANTED.
Capital to Handle Extensive Gold Mines.
JAMES ARTHUR, Cornucopia, Oregon.

WANTED.
Position as Superintendent or Assistant Superintendent of Copper Mining and Smelting Works.
Competent Smelter, Assayer, etc. Understands handling men; speaks Spanish; willing to go to Mexico or South America; best references. Address COPPER, this office.

..CRIPPLE : CREEK..
FOR SALE—CYANIDE PLANT,
100 tons daily capacity: in first-class condition to handle Cripple Creek ores.
Plant in full running order, with all latest improvements. Address JOHN S. MACBETH, Equitable Building, Denver, Colorado.

W.&P. BUILDING PAPER.
Insulating. Water proof. Sanitary. Vermin proof.
Tarred Felts, Roof Paints, Boiler & Stack Paints.
PACIFIC REFINING & ROOFING CO.
113 New Montgomery St., S. F.
Correspondence solicited.

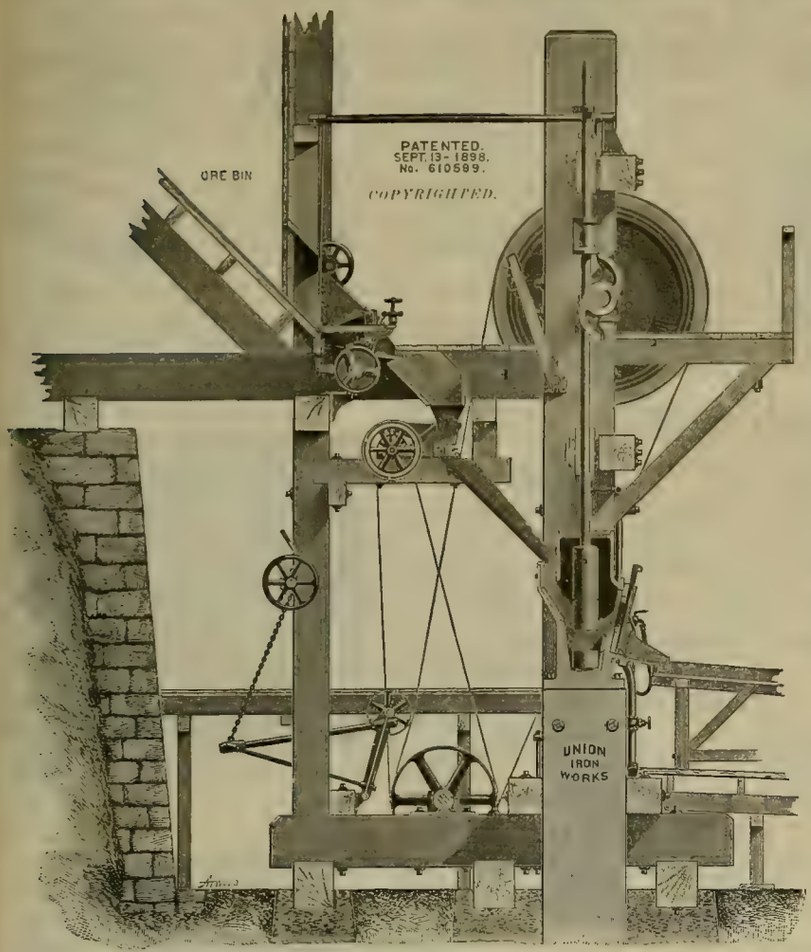
UNION IRON WORKS,

222 Market Street, San Francisco, Cal.



THIS ILLUSTRATION

Shows our patent Improved Stamp Mill, with Secondary Crusher, which increases the capacity of the ordinary stamp battery from 25 to 30 per cent.

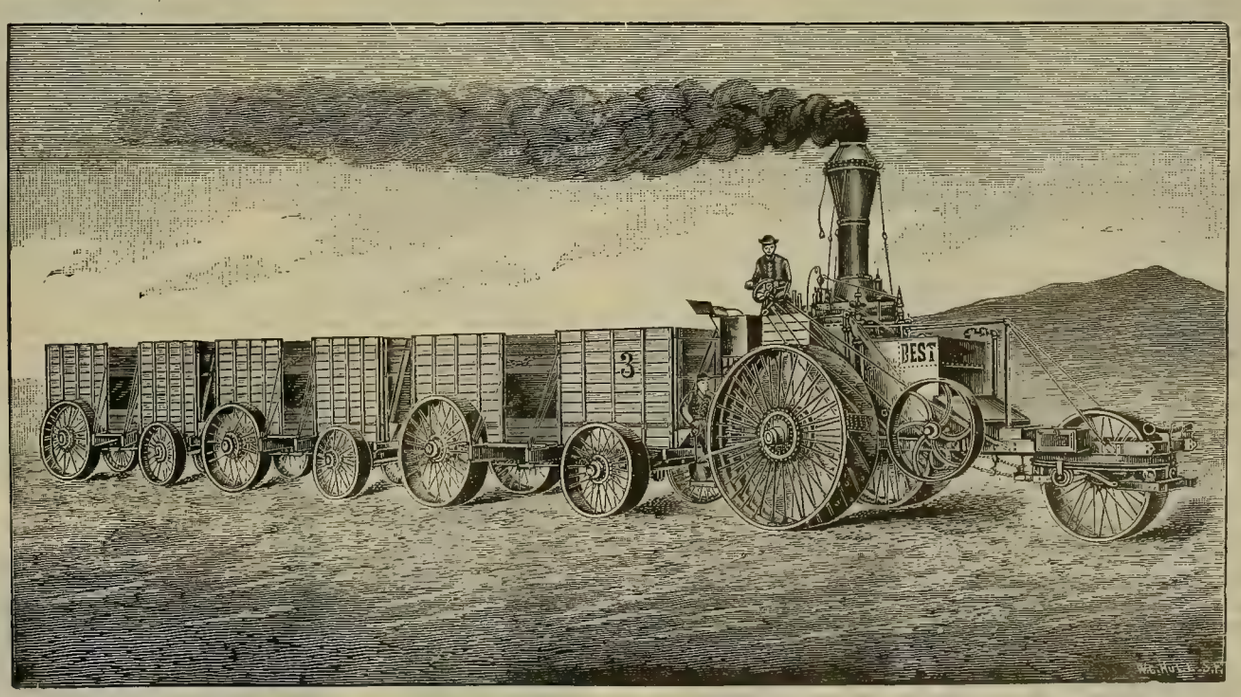
We respectfully invite the attention of those contemplating the erection of new mills to this practical improvement.

For particulars address

UNION IRON WORKS,

222 MARKET ST., SAN FRANCISCO, CAL.

A REVOLUTION IN FREIGHTING.



THESE WAGONS ARE ESPECIALLY ADAPTED FOR STEAM FREIGHTING; CAPACITY OF TRAIN 50 TONS.

"The Daniel Best" 50-Horse Power Traction Engine.

The most powerful and only Successful and Practicable Road Engine in the World. Over sixty of them in use in this State, and they are being Successfully and Profitably Employed in Hauling Log Lumber, Ore, Salt, Borax and other kinds of freight.

The work is being done **FIFTY PER CENT** Cheaper than it is possible to do with Animal Power. They can be operated over any ordinary road where it is practicable to use mules or horses, doing the same work. They can ascend or descend grades as much as 20 to 30 inches to the rod, hauling their loads of 35 to 40 tons, depending upon the condition of the roads; loads may be increased to even greater amount on moderately level roads.

Send for descriptive Circulars and price List of Wagons and Engine. We solicit correspondence. No trouble to answer questions.

Estimates made for complete Steam Freighting Outfits. Address

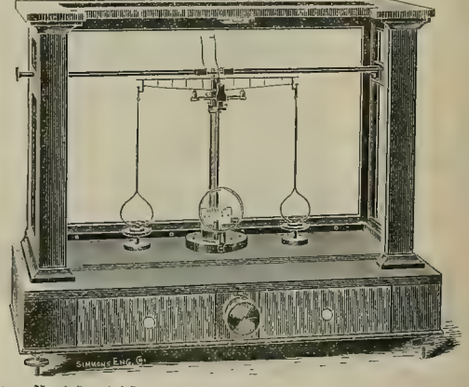
The above illustration shows the method of holding and sighting BRUNTON'S PAT. POCKET MINE TRANSIT, when taking courses or horizontal angles The construction is such as to permit of simultaneous sighting and reading. No tripod or Jacob's staff is necessary, and an operator, after becoming accustomed to its uses, can take the Transit from his pocket, take a reading and replace the instrument before a sighting compass can be placed. The most accurate and reliable pocket instrument on the market. Send for illustrated Catalogue B to



No. 1 Special Button Balance with 8-inch beam. Sensibility 1-200 Milligramme. For very accurate weighings. Among the well-known smelters using this balance are the following: GLOBE SMELTING & REFINING CO., Denver, Colo., U. S. A.; CANADIAN SMELTING WORKS, Trail, B. C.; MT. LYELL MINING & RAILWAY CO.'S Reduction Works, Penghana, Tasmania.
For full description of this and other balances send for Catalogue A to

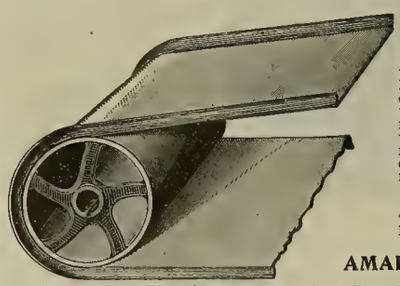
SPADONE'S CONCENTRATOR BELTS.

PATENTED.



This illustration shows the edge flanging outwardly as it passes over the pulley. This relieves the strain from the top and bottom of the edge by directing the strain automatically to the inside face surface of the edges. Heretofore all belts have been so constructed that when they pass over the pulleys or rolls, a direct strain comes upon the top or at the base of the edges, causing the edges to break away from the body of the belts in a very short time. *We avoid this Mechanical Defect by our Spadone Curved Edge.* Belts made to fit any machine—4, 5 and 6 feet wide. Prices and samples on application.

AMALGAM PLATE CLEANERS.

Our Amalgam Plate Cleaners are made of Pure Rubber in moulds, thus insuring a plate cleaner which will not scratch the plates and a perfect edge which will clean the Amalgam plates evenly. They are made 6 inches long, 3 inches wide and ½ inch thick, making a convenient size to handle. Price by mail to any address, each 75 cents. Correspondence solicited.

Send us your order for Water, Air Drill, Steam, Suction and Fire HOSE, RUBBER BELTING, RUBBER PACKING and LEATHER BELTING.

WRITE FOR PRICE LIST.

UNFAIR COMPETITION.

Our recent announcement that inferior goods had been sold and billed on the coast as our goods, and that our trade-mark numbers had been counterfeited, has disclosed an even greater extent of these practices than we had supposed to exist. To make the resulting damage to the reputation of our goods as small as possible and to protect our would-be patrons we repeat:

All our catalogue goods, except those listed by us as manufactured by others, are stamped with our name "Keuffel & Esser Co." or our initials "K. & E. Co." and where there is room for it, with our trade mark Our German drawing instruments bear only the trade marks or **We never stamp our goods with catalogue numbers only,** and goods so stamped are therefore not ours. All our goods are fully warranted to conform to the description we give of them in our catalogue and to be of the quality and grade specified. We make some lines of cheaper goods for the jobbing trade, but they differ from our catalogue goods in quality and appearance. These inferior goods are not stamped with any of our trade marks. Our catalogue goods are not furnished to any dealer or agent without our complete stamp as described above, and any claim that we furnish our catalogue goods by special arrangement without our stamp is therefore an attempt to deceive. Our special papers in rolls or sheets

Duplex Universal Anvil Paragon Normal

are watermarked or stamped along the edge with their name. Any claims that our papers are furnished by us in bulk without these names or that these papers have been obtained otherwise than through us, are absolutely false. We will thankfully accept any information bearing on the counterfeiting of our trade-mark numbers or the palming off of other goods as ours.

Very respectfully, KEUFFEL & ESSER CO.

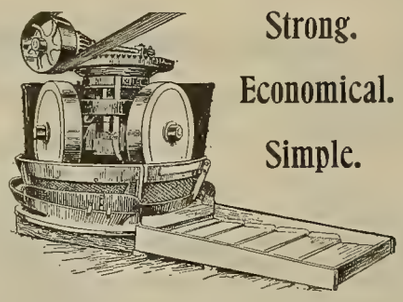
THE BRYAN ROLLER QUARTZ MILL.

We are the sole manufacturers of this Mill. A test made by the Bullion-Beck Co. of Eureka, Utah, with this and the Huntington Mill proved conclusively every claim we made for the Bryan Mill, viz: that the Bryan would crush more ore with less repairs, less power and less slimes than any Mill made. Result—they are now operating three of the five-foot Bryan Mills and find them superior and more satisfactory than any Mill they ever u ed. L. C. Trent & Co., who had formerly sold the Huntington Mill, immediately manufactured a Mill infringing our patent. Suit brought in the U. S. Court resulted in a verdict in our favor, and we shall prosecute to the full extent of the law any infringement of any character whatsoever in the MAKING, USING or SELLING of the same.



Strong.
Economical.
Simple.

MANUFACTURED BY

The BRYAN MILL is constructed on the principle of the Chili Mill, except it has three rollers arranged to run in a continuous discharging pan. It crushes either gold or silver ores. It consists of an annular cast-iron mortar with fixed steel dies arranged in the path of its three crushing rollers. Power is applied direct from a pulley through a bevel gear and pinion secured to stationary center post. We present a few of many advantages it possesses over any other Mill: Larger screen capacity and free discharge. Amalgamates a larger percentage of gold. Quickly and cheaply erected; with regular feed and proper flow of water requires little attention. Crushes hard or soft ore with smaller amount of power per ton and less wear and tear of machinery.

Send for Catalogue No. 8.

PATENTS

DEWEY, STRONG & CO'S PATENT AGENCY.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American reports, with full copies of U. S. Patents since 1872. All worthy inventions patented through DEWEY, STRONG & CO.'s Patent Agency will have the benefit of a description in the *Mining and Scientific Press*. We transact every branch of patent business, and obtain patents in all countries which grant protection to inventors. The large majority of U. S. and foreign patents issued to inventors on the Pacific Coast have been obtained through our agency. We can give the best and *most reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and circulars free.

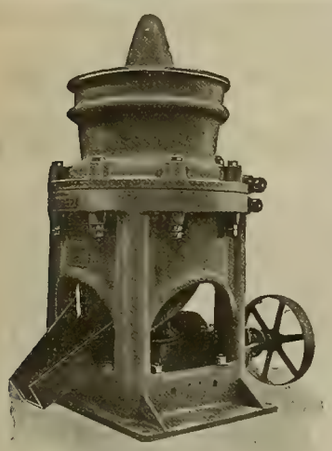
We also manufacture all kinds of Ore Milling Equipments for Amalgamation, Concentration, Cyanide and Chlorination Processes.

(SEE PAGE 246)



GATES FINE CRUSHER.

The result of ten years' solid work. Success at last. What we wanted, and the public demanded, was a Gates Gyratory Rock and Ore Breaker (always adjustable and indestructible) so modified in design as to make one-half-inch product from three-inch sizes, rapidly and cheaply. The H Fine Crusher will do this work. It takes the place of expensive big rolls and often prepares ore, without further crushing, fine enough for coarse concentration or cyaniding. In any event, it is the greatest and best intermediate machine between the coarse breaker and the pulverizer.

Ask for No. 1 Catalogue. :: GATES IRON WORKS, Dept. UU, 650 Elston Ave., CHICAGO.

Market Reports.

The Markets.

SAN FRANCISCO, March 2, 1899.

SILVER. — London, 27¾d; New York, 59⅛; San Francisco, 59¼; Mexican Dollars, 47⅛@48. New York exchange, sight, 17½; telegraphic, 20 cents premium.

LEAD.—New York reports $4.30 bid, $4.35 asked; brokers' price, $4.20.

Local, pipe, 7@7¼c; sheet, 7@8c; pig, 6¾c; bar, 7c.

COPPER.—New York reports Lake unchanged, $17.75 bid, $18 asked. Local, bar, 21½c per lb.

Copper has risen so rapidly in market value during the past sixty days that there is a feeling among the trade, says the Boston News Bureau, that 18 cents for copper means a sensitive if not a dangerous market. The copper market has its pros and cons, but, whatever view is taken, it must be admitted that there is a legitimate basis for the strong movement which has taken place in the copper markets of the world. But, while recognizing the fact that the operation of the law of supply and demand in this case has certainly conduced to the recent advance in the price of this commodity, there is a danger that the excessive rise, if pushed too far, may terminate in a disastrous reaction.

While there are legitimate reasons why copper should command the highest market experienced in a period of ten years, there are manipulators who have taken advantage of the present favorable position of the metal to boom and inflate copper stocks to an enormous degree, giving many of them a value far beyond anything ever known before, and raising quotations of shares to a pitch that would seem indicative that some investors have lost the ability to calculate values and the relation between the producing capacity of a property, its earning power, its market worth and the investment prospects. How much copper has any of the mining companies sold at 18 cents? Producers were so well sold up when the market was 12, 13 and 15 cents that they had comparatively little copper to sell when higher figures were obtainable. Therefore to figure out earnings based on a market at 18 cents, when deliveries are taking place at 13 cents or over, is not strictly correct. The heavy buying was done before copper reached 18 cents and at present Europe cannot pay the parity of this market, while neither domestic nor foreign buyers show much boldness in making new purchases at present prices, except for prompt shipment.

A London metal house comments in an interesting way on the position of copper as follows: "The market has continued to advance by leaps and bounds. The reactions have been small and very short-lived. On Feb. 3rd cash copper touched £74 7s 6d, but declined to £71 15s, which is the first serious break that has taken place. Forward delivery is at a considerable discount. What this advance means is worth consideration. It means that the profit to copper producers is raised from about £6,000,000 per annum to about £12,000,000. Is this necessary to secure an adequate supply? We should say certainly not, for on the basis of last year's prices increased mining activity was set going, which competent authorities calculate at 50,000 tons for '99, or about 15%. We further wish to point out that, so far as fine copper is concerned, we have now reached the level which ruined the Secretan syndicate. By maintaining fine copper at the basis of £75 to £80 for a year, the visible supplies were raised from 42,500 tons to 104,000 tons in the twelve months. Who wants to see a repetition of that folly? In the neck-and-neck race between consumption and production last year, the excess of the former was only 1½%. How easily, on such a narrow basis, can the position become seriously reversed? Already India is sending back ingot copper, and very large contracts here have been arranged for shipment from Japan. As to the American syndicate, it is merely a sink for superfluous cash. It is vague in its purposes so far as disclosed, and does not contain either the Anaconda or Calumet mines, nor, so far as we know, any of the leading European. We say without the slightest hesitation that any advance over £80 per ton is pernicious and opposed to the true interests of stability in the trade."

IRON.—American, soft, $22@24 per ton; Scotch, $27. Local bar, 2½c per lb.

TIN.—Pig, 30c per lb.; Bar, 29c. New York reports "unchanged" at $17.

ANTIMONY.—16.

BABBITT METAL.—No. 3, 8c.

QUICKSILVER.—Local, $42; export, $39.00 @39.50; carload lots, special rates.

California quicksilver mines are largely owned and managed by Boston men. The three companies mentioned below are organized under the laws of Wyoming. The News Bureau says: "There are no cheaper stocks to-day than Boston's quicksilver properties, although it is useless to call attention to them as probably 1000 shares of any one of them could not be purchased without advancing the price materially."

All three of the companies are organized under the laws of Wyoming. It is the policy of the management which operates these properties to keep at least $100,000 cash as reserve in each treasury. The mines are opened up years ahead.

The situation as regards quicksilver to-day is phenomenally strong. The visible supply in this country does not exceed 4000 flasks. The price to-day is strong at $44 per flask (76½ pounds).

We give in the annexed table a few items which may be interesting regarding these three companies:

	Napa.	*Ætna.*	*New Idria.*
Share capital.....	100,000	100,000	100,000
Par value.....	$7	$5	$5
Present price.....	8½	4	11
Dividend per annum.	80c	40c	80c
Investment returns.	9½%	10%	7¼%
Dividends to date..	$990,000	$170,000	$100,000

The Napa was not floated by present managers, but was bought from former owners and old capitalization retained. The Ætna was floated at $2.50 per share, and the New Idria floated about two years ago at $5 per share; 2000 shares sold yesterday at $11 per share. The stocks are very closely held and frequently transfers are not made for months at a time.

POWDER.—F. o. b., San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15¼c; less than one ton, 17¼c. No. 1* 60%, carload lots, 13¼c; less than one ton, 15¼c. No. 1** 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2* 35%, carload lots, 9¼c; less than one ton, 11½c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

FUSE.—Triple tape, $5.10 per 1000 feet; double tape, $4.35; single tape, $3.45; Hemp, $3; Cement No. 2, $4.35; Cement No. 1, $3.45.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9.

COAL.—San Francisco coast, yard prices:

Wellington	$8 00	Coos Bay	$5 00
Seattle	6 00	Southfield	7 50

Cargo lots, Eastern and foreign:

Wallsend	$ 7 50	Cumberland	$ 9 00
Brymbo	7 50	Cannel	9 50
Pennsylvania, hd..	14 50	Welsh Anthracite.	12 50
Scotch	8 00	Rock Springs	7 60

COKE. — Foreign, $13; domestic, $12 per ton.

CHEMICALS. — Cyanide of potassium, jobbing, 30 @ 31c per lb.; carloads, 29c; in 10-lb. tins 37c; sulphuric acid, 2¼c per lb. 66° B.; soda ash, $1.60 per 100 lbs. 58%; hyposulphite of soda, 2¾c per lb.; blue vitriol, 4¼c per lb.; borax, refined, 5@6c per lb.; chlorate of potash, 9½@10c; roll sulphur, 2¾c; alum, $1.90@2.00; flour sulphur, French. 2½@2½c; California refined, 1½@1¾c; nitric acid, in carboys 8c per lb; caustic soda, in 10-lb. tins 15c per lb.; Cal. s. soda, bbls., 65c; sks., 60c ₱ 100 lbs; chloride of lime, spot, 2.10 @2.25c; saltpeter, 15c; chlorate of potash, 25c; caustic potash, 12c.

CANDLES.—Electric Light Candles—6s, 16 oz., 7½c; 6s, 14 oz., 6½c; 6s, 12 oz., 5½c; 6s, 10 oz., 4½c; Granite (Mining) Candles—6s, 16 oz., 8¾c, 6s, 14 oz., 7¾c; 6s, 12 oz., 7¼c; 6s, 10 oz., 6½c. Paraffine Wax Candles—1s, 2s, 4s, 6, 12s, white, 8c; colored, 9c.

NAILS.—List per keg: No. 20 to 60d, wire, $2.50; cut, $2.35; 10 to 20d, wire, $2.55; cut, $2.40; 8d, wire, $2.60; cut, $2.45; 6 and 7d, wire, $2.70; cut, $2.55; 4 and 5d, wire, $2.80; cut, $2.65; 3d, wire, $2.95; cut, $2.80; 2d, wire, $3.20; cut, $3.05. In carload lots, 10c per keg less.

Assessment Notices.

JUNCTION MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Tuolumne County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 4th day of February, 1899, an assessment (No. 23) of three (3) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, 106 Leidesdorff street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 13th day of March, 1899, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on MONDAY, the 3rd day of April, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CALVERT MEADE, Secretary.

Office—106 Leidesdorff street, San Francisco, California.

ORLEANS MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Grass Valley, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 8th day of February, 1899, an assessment (No. 8, new series) of seven (7) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 324 Pine St., San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 14th day of March, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 5th day of April, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

GEO. P. THURSTON, Secretary.

Office—324 Pine St., San Francisco, California.

DELINQUENT SALE NOTICE.

MARGUERITE GOLD MINING AND MILLING Company.—Location of principal place of business, San Francisco, California; location of works, Auburn, Placer County, California.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 12) levied on the 2nd day of January, 1899, the several amounts set opposite the names of the respective shareholders, as follows:

The latest and best books can be had from the Book Department of the MINING AND SCIENTIFIC PRESS at best prices. ALL BOOKS SENT POSTPAID. Following is a partial list:

ASSAYING:—PART I—GOLD AND SILVER ORES.
Third edition; Rewritten and Improved by the Author, C. H. Aaron; 130 pages, illustrated....$1

ASSAYING:—PARTS II & III—GOLD AND SILVER BULLION, LEAD, COPPER, TIN, ETC
Latest edition; 161 pages, illustrated, cloth. Much of the original text replaced by new matter....$1 75

PROSPECTOR'S FIELD BOOK AND GUIDE:
By H. S. Osborn....$1 50

ROASTING OF GOLD AND SILVER ORES AND THE EXTRACTION OF THEIR RESPECTIVE METALS WITHOUT QUICKSILVER:
Second edition; Guido Kustel, M. E.; 156 pages, with illustrations of furnaces, supplements and working apparatus....$3

PRACTICAL TREATISE ON HYDRAULIC MINING:
By Aug. J. Bowie, Jr. On the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on heavy grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc....$5

PRACTICAL HYDRAULICS:
A book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers and Irrigators. By P. M. Randall. Contains useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulæ, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules and tables are prepared. Is specially applicable to the Pacific Coast....$2

MODERN COPPER SMELTING:
E. Dyer Peters, Jr. Eighth edition. Rewritten and enlarged. Profusely illustrated....$5

STAMP MILLING OF GOLD ORES:
By T. A. Rickard, M. E. An actual record of milling practice in this and other countries. Deals with the erection and management of mills, and contains many helpful suggestions. Well illustrated. Cloth....$2 50

MINERS' POCKETBOOK:
A reference book for miners, mine surveyors, geologists, mineralogists, millmen, assayers and metallurgists. By C. G W. Lock. 472 pages, illustrated, flexible leather....$5

MANUAL OF MINING:
For the use of Mining Engineers and Technical Schools. Treating of Preparatory and Exploratory Work, Methods of Mining, Hoisting Machinery, Pumping, Ventilation Shafts, Tunnels, Blasting, Timbering, etc., etc. By Prof. Magnus C. Ihlseng, E. M., Ph. D. Third, revised and enlarged, edition. 548 pages, 8vo., cloth....$4

THE EXPLORER'S AND ASSAYER'S COMPANION:
Third edition. By J. S. Phillips. A practical exposition of the various departments of Geology, Exploration, Mining Engineering, Assaying and Metallurgy. An exceeding valuable work....$6

THE METALLURGY OF GOLD:
By M. Eissler. Profusely illustrated....$5

CYANIDE PROCESSES FOR GOLD AND SILVER ORES:
By E. B. Wilson, E. M....$1 50

SKELETON MINING REPORT:
Of great practical value to miners and mine owners in making a comprehensive report on mining properties. Useful and convenient to mining engineers as a field notebook. Price, postpaid....50c

QUARTZ OPERATOR'S HANDBOOK:
By P. M. Randall....$2

ALLOYS:
Thurston, 2nd edition....$2 50

ASSAYING:
Furman, 4th edition....$3

HIGH EXPLOSIVES:
Eissler....$4

GOLD ORES:
Treatment of; O'Driscoll....$2

MINERALOGY:
Brush & Penfield, revised edition, $3 50; Dana, 6th edition, $12 50; Dana, for beginners, $1 50; Dana, Mineralogy and Petrography, 12th edition....$2

MINERALS:
"How to Study Them," Dana, 2nd edition, $2; Dana, American locality of mineral, 6th edition....$1

MINING:
Ihlseng, from lectures in Colorado School of Mines....$4

ORE DEPOSITS:
Phillips, revised edition by Louis....$7

METALLURGY:
Eggleston, Silver, Gold and Mercury, 2 vols. $15

If you do not find what you want in above list send for catalogue and price list, sent postpaid to any address. **Book Department Mining and Scientific Press, 330 Market street, San Francisco, Cal.**

January 2, 1897.

"The roasting is invariably good. We can do 80 tons per day to 0.13% sulphur, when everything runs smooth. Our month record which, of course, includes all delays, is 1700 tons, from 1.94% sulphur to 0.16%."

February 19, 1897.

"Our furnace is now running very nicely indeed, averaging 90 tons per day to 0.10% sulphur, and doing excellent work; in fact, it has improved right along and we are highly pleased with it.
"For 24 hours ending 7 A. M. to-day 102 tons were roasted."

The **ROPP FURNACE** is now in successful operation at the following reduction works: The Hanauer Smelting Works, Salt Lake City, Utah (one furnace); The Metallic Extraction Co., Cyanide, Colo. (one furnace); The Colorado-Philadelphia Reduction Co., Colorado City, Colo. (three furnaces); The Selby Smelting & Lead Co., Selby, Cal. (two furnaces); The Mount Morgan Gold Mining Co., Rockhampton, Queensland (one furnace); Broken Hill Proprietary Co., Broken Hill, New South Wales (four furnaces); Puget Sound Reduction Co., Everett, Washington; Colorado Ore Sampling & Reduction Co., Cripple Creek, Colo.; Consolidated Kansas City Smelting & Refining Co., for the Arkansas Valley Smelting Works, Leadville, Colo.; Robert Lanyon's Son's Spelter Co., Iola, Kansas (two furnaces); Mountain Copper Co., Ltd., Keswick, Cal.

Catalogue on Application.

MINE BELL SIGNALS.

Adopted, Used and in Force in Accordance with State Law.

For the convenience of our readers in the mining counties we print in legal size, 12x36 inches, the Mine Bell Signals and Rules provided for in the Voorhies Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We furnish these Signals and Rules, printed on cloth so as to withstand dampness. **50 Cents a Copy.**

Avalanches Among Colorado Gold Mines.

A striking and peculiar characteristic of Colorado's mines is that the lowest altitude of a Colorado mine is about equal to the highest altitude of a California mine. In Colorado a mine is rarely less than 8000 feet above the sea: in California a mine is rarely more than 8000 feet above the sea, the bottoms of the shafts of many of California's greatest gold producers being below the level of the sea, while in Colorado the collar of the shaft is in many cases at an altitude of 12,000 feet above the ocean level.

The Colorado miner surmounts many disadvantages and, despite the obstacles of cold and snow, usually continues development work throughout the entire season. In such winters as the present one, however, the unusual snowfall occasioned cessation of work in numerous high mines, and in several instances caused loss of life and property. In a few reported casualties snowslides wreaked ruin.

A recent number of the Telluride *Journal*, published near the summit of one of the highest ranges of the Rocky mountains in San Miguel Co., Colorado, briefly describes an avalanche that on February 12th at Ophir wrecked a stamp mill and killed the mill man, J. C. Vardell. (A week after came the brief statement from Ophir, Colo.: "Jim was killed in the snowslide, stop his paper.") Accordingly the name of the unfortunate Colorado miner was taken from the mail list of the MINING AND SCIENTIFIC PRESS. Poor fellow! he lost his life trying to save others, as many a brave miner has done before. A picture of the Ophir tunnel is presented, as it appears on the trail to Smuggler. It was the Carribou mill that was wrecked, and in it Vardell was killed. In its account the *Journal* says: "The slide came down on Silver mountain, starting near the summit, up in the vicinity of the Suffolk mine. It ran across the valley with its force nearly spent, striking the Carribou mill just at the foot of Yellow mountain and crushed in the lower story but did not knock the mill down. The mill was running and a number of men were at work on the upper floors. A man who was on the ground floor had just been called upstairs by one of the workmen to fix some machine that had become clogged. He left Mr. Vardell standing at the foot of the stairs and had only reached the third floor when the timbers carried by the slide crashed into the lower rooms killing and burying Mr. Vardell. The snow was packed so hard it was slow digging and a hose under high pressure was used in digging for the body which was reached about 11:30 Monday morning. The body was badly crushed under heavy timbers and death must have been instantaneous."

On this page also appears a portrayal of the Suffolk mill, a 40-stamp concern, the largest mill in Ophir. It was from the mountain in the background that the fatal snowslide started. Not in a generation has there been such a heavy snowfall throughout Colorado as in the early weeks of '99, and while it insures abundant water for the season, the discomfort and, as in the above cases, the resultant disaster make dismal the present condition of many a miner in the high altitudes of that State.

OPHIR TUNNEL, COLORADO, ON THE WAY TO SMUGGLER. (THE FIRST BUILDING AND SHED AT THE BOTTOM OF THE PICTURE ARE AT THE ENTRANCE TO THE TUNNEL.)

THE SUFFOLK MILL, OPHIR, COLORADO. (WHERE THE FEBRUARY 12TH SNOWSLIDE STARTED.)

TABLE OF CONTENTS.

ILLUSTRATIONS.—Ophir Tunnel, Colorado, on the Way to Smuggler; The Suffolk Mill, Ophir, Colo., Where the February 12th Snowslide Started, 257. Boiler-Room of the Harvard Power Station; Engine-Room of the Harvard Power Station, Boston, Mass., 260. La Patera Mine, Santa Barbara, Cal.; Lake Formed by Subsidence of Land, 261. Latest Mining and Metallurgical Patents, 263. The Formation of Glacial Lakes of the First Class; Glacial Lakes of the Second Class; Glacial Lake of the Third Class; Dam Formed of Glacial Detritus; Bedrock, 265. Dry Blower at Work; Dry Blowing Machine, 266.

EDITORIAL.—Avalanches Among Colorado Gold Mines, 257. Activity in Copper Development; "Experts" in the Field; Greater Rigidity in Mortar Blocks; A Few Metal Statistics; The Ætna Tunnel at Leadville, Colo.; Relation of Depth and Values, 258.

MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 267-68-69.

THE MARKETS.—The Local Markets; Mining Share Market; Sales in San Francisco Stock Board, 282.

MISCELLANEOUS.—Concentrates, 259. A Boston, Mass., Electric Power Station; Wave Vibrations; Some Experiences of a Working Miner, 260. The Genesis of Petroleum and Asphaltum in California; The Feedwater of Stamp Mills, 261. A Mine Beyond the Arctic Circle; British Columbia Mining Requirements; An Automatic Accountant; Capacity in Gallons of Circular Tanks, Cisterns, Etc., for Each Foot in Depth; Time Allowed for Assessment Work; Effect of the Smelter Trust; A Steel Roadway; A New Process to Preserve Wooden Telegraph Poles; Electric Lamps in Philadelphia, 262. Latest Mining and Metallurgical Patents; The Naval Repair Ship; An Automatic Railway, 263. The Smelting of Ore in the Kootenays; A Long Canoe Trip; Crushing Rolls; Experiments on Nickel-Iron Alloys, 264. Glacial Agency in Lake Formation; The Science of Prospecting, 265. The Alluvial Deposits of Western Australia, 266. Industrial Notes; Personal; List of U. S. Patents for Pacific Coast Inventors; Notices of Recent Patents; California Mining Incorporations; Obituary, 270. Recently Declared Mining Dividends; Catalogues Received: Commercial Paragraphs, 282.

It is now suggested that a medal be struck and presented to each of the Sacramento, Cal., legislators who "held out" for Burns for U. S. Senator. Good idea! Make it of beaten brass.

There is now in the field a small army of "experts," whose business it is to go about the country making examinations of mining claims in all stages of development. Men thus engaged have assumed a great responsibility and in passing judgment on mines have not only their own interest at stake but their opinion usually affects many others. A realizing sense of this responsibility seems to make some men overcautious and others pay little heed to the result of their report, being satisfied to receive the agreed fee for their opinion. Fortunately the tendency seems to be towards the conservative side, for the most prominent men in the business are generally well-known conservatives, and the lesser lights, finding that a bad error of judgment is likely to result disastrously in the future, are falling in line and condemning almost everything they go to see, and perhaps by so doing make fewer mistakes. A would-be investor may have occasion to look back with regret at a lost opportunity, but such regrets are of a somewhat different nature from those occasioned by large sums lost on unsuccessful "good things."

In driving the Yak tunnel at Leadville, Colorado, under Breece Hill, an almost insurmountable obstacle has been found in the Pilot fault which crosses the line of the tunnel. The rock in the fault plane is crushed and heavy. Timber sets are broken and forced out of position by the persistent encroachment of the moving mass of rock. In the endeavor to overcome the difficulty, and to relieve the timbers, the ground has been repeatedly cut away and the space filled with timbers. The latest reports from the tunnel, which is now in over 7000 feet, are to the effect that the timber now in place looks as though it would stand. Everyone acquainted with heavy swelling ground knows that timber, no matter how arranged, can only sustain the enormous pressure for a brief period. Perhaps a few weeks, oftener but a few days, when it must be replaced. California miners are familiar with the irresistible pressure of the swelling slate walls in many of the mines. New timbers are required constantly to keep drifts and shafts open. It has become a recognized fact among mine superintendents that it pays to sink shafts in the hard country rock at double the expense of sinking in the soft fissure, for when the shaft is completed the expense of keeping it open is practically nothing, while in swelling ground the expense continues until the shaft is abandoned. Timbers have to be renewed from time to time at various points in shafts sunk in hard rock, but not for several years after being put in place. The Yak tunnel is run through hard ground, but in the plane of the Pilot fault they have found the difficulty which has cost so much time and money. When such conditions are met in the progress of underground development of mines it would seem that steel frames either arched or angular could be substituted to good advantage for wood. The first cost would, of course, greatly exceed that of wood, but if it were found to give the desired permanent support it would eventually prove to be cheaper than timber. In England and Germany iron and steel have been used for supporting mine workings for years.

A Few Metal Statistics.

History is precept teaching by example in a large way. Present prophecies regarding prices of metals, etc., may, in some cases, be modified by the presentation of a few statistics, believed to be accurate. The figures on lead and iron indicate the beats of the nation's industrial pulse. Those pertaining to gold and silver are additionally suggestive when widespread political action is taken into account. Men who insist that copper supply cannot equal demand, and that its price must constantly appreciate, might with profit note the figures relative to that important metal. For purposes of convenience the figures are necessarily condensed:

ANNUAL PRODUCTION FOR THE LAST THIRTEEN YEARS OF FIVE PRINCIPAL METALS.

	1886.	1887.	1888.	1889.	1890.	1891.	1892.	1893.	1894.	1895.	1896.	1897.	1898.
Pig iron, million tons.....	5.68	6.42	6.49	7.60	9.20	8.28	9.16	7.12	6.66	9.45	8.62	9.65	11.71
Silver, million ounces.....	39.45	41.27	45.78	51.35	54.50	58.33	63.50	60.00	49.50	55.73	58 83	53.86	64.06
Gold, million ounces.....	1.88	1.85	1.60	1.59	1.59	1.60	1.60	1.74	1.91	2.25	2.57	2.77	3.11
Copper, million pounds.....	161	185	231	231	265	296	353	340	365	393	460	492	545
Lead, thousand tons.....	131	147	152	156	144	179	174	164	159	170	188	208	217

The above figures constitute a striking compendium of the industrial history of the nation during the period under discussion, being as exact as a barometer. Silver was steadily prosperous till '93, since which time it has been erratic, till '98. It is incidentally noticeable, in this connection, that last year silver fluctuated, proportionately, in price less than any other metal, and less than any other year since records of silver's price have been kept. The year that marked silver's demonetization showed an increase in gold production that has since gone steadily forward nearly 10% annually. Copper shows the greatest percentage of increased output—over 338%. The great demand swept away the enormous reserves and called for a tremendously increased supply. This increased electrical and general industrial demand, a genuine business requirement, was a boon and a boom to copper on hand and copper stocks. Whether such demand is destined to continue, or whether copper is to ultimately drop considerably below its present figure, is a question that does not admit of ordinary success in present effort to answer.

There is a tendency on the part of quartz-mill builders to secure greater rigidity in mortar blocks. Twenty years ago solid blocks of timber were used for this purpose, and, where single blocks could not be found of sufficient size, two or three blocks were bolted together. Later the built-up blocks constructed of 2-inch planks securely spiked together were tried, and, being found satisfactory, came generally into use and are usually better than blocks made from large timbers. More recently several mills have been built in which concrete mortar blocks were introduced. These latter have not been in use long enough to determine whether they are in any way superior to wooden blocks or not. Iron mortar blocks are now being tried, with what result the future must determine. Mortars are much longer lived now than formerly, since they are cast somewhat heavier and are provided with false bottoms and side linings to protect all parts exposed to wear, consequently the necessity for replacing old mortars with new is less frequent, and a mortar block which will last as long as the mortar, at least, becomes very desirable. The new 500-stamp Alaska-Treadwell mill is supplied with iron mortar blocks weighing about 10,000 pounds, resting upon broad concrete foundations.

Relation of Depth and Values.

At the conclusion of the annual address of Mr. James Stirling, government geologist for Victoria, delivered recently in Melbourne, Australia, before the Geological Society of Australasia, Mr. E. L. Rosman, in seconding a vote of thanks to the lecturer, remarked that the thanks of the society were due to Messrs. Bell and Watson and Mr. George Lansel. "for the enterprise shown by them in exploding the idea of geologists that payable gold could not be got at a greater depth from the surface than 400 feet." Mr. Stirling, in reply, pointed out that when the assertion alluded to was made by Professor McCoy and Mr. Panton, Dr. Selwyn publicly stated his opinion to the contrary, and refused to sign the memorandum submitted to Parliament on the subject.

The statement elicited a reply from Sir Frederick McCoy, who wrote to the Melbourne daily papers to the following effect: "I never wrote, said, or thought any such thing, and I challenge anyone to produce any such statement. I believe, as a rule, the upper portion of gold veins is richer than the lower, but that there is no limit to the depth at which traces of gold may be found."

The latter clause of the above, coming from such a distinguished source, leads to the inquiry, "Do gold-bearing veins deteriorate in value with depth?" As the depth at which veins become so impoverished as to be valueless has never been reached in many good mines in the United States, it is a matter of theory, unsubstantiated by fact, that mineral veins deteriorate with depth. The relation of value to depth is always determined by economic conditions. A few years ago mines worked to the depth of 1000 feet were looked upon as approaching the limit at which mines could be practicably worked; but the shafts have gone steadily deeper until now there are many mines more than 2000 feet deep still paying, and with no noticeable falling off in value. In California there are a number of mines near or below the 2500-foot mark, and these, with a single exception, are all paying, and at one of these mines at least—the Kennedy at Jackson, Amador county—a new vertical shaft is being sunk through which the mine will probably be worked to a depth of 4000 feet or perhaps deeper. Mining at such great depths is somewhat more expensive than nearer the surface, for the reason that they require heavier and more expensive hoisting and pumping machinery, which, requiring more power, are operated at greater expense. But as an offset to this, more material can be hoisted in a given time through a well-equipped vertical shaft than through some of the old inclines in which skips are used.

In California mines the ore, taking one level or shoot with another, averages in any particular mine about the same. Ore of every grade can be found on almost any level, though some levels have no ore at all. Undoubtedly there is a depth at which any mine will cease to pay and that depth will be found where the cost of mining equals or exceeds the commercial value of the output, and this depth will vary with the local condition. In some mines extreme heat is the prohibitory factor, in others too much water, and in some both. The causes are always of a physical character in gold mines, for the market price of the metal does not fluctuate. Because the operating expense of a mine exceeds the value of the product, which at a higher level may have afforded a profit, does not determine that the ore has deteriorated, but that the expense has increased.

It is true of many veins, particularly those soft, porous "honey combed" zones, that they are often found richest at the surface, but this is a local condition which should not enter into the general discussion of the relation of depth to the gold value contained in veins.

Concentrates.

THERE is more friction on a wood pulley than on a turned cast iron pulley.

CHALK may be used to advantage on the brakes of hoisting engines to prevent slipping.

KEYS for securing pulleys, cams, etc., to shafting should taper one-sixteenth of an inch in 4 inches.

RUBBER belts must not be greased. To prevent slipping use boiled linseed oil and sprinkle a little chalk.

DURING the week ending Feb. 25 fifteen new mining companies filed articles of incorporation in Spokane, Wash.

READERS remailing an issue of this paper to any part of the U. S. should affix 1 cent postage: foreign, 2 cents.

BATTERY water which is run into settling tanks or reservoirs may be pumped back and reused at a loss of about 25%.

THERE has been no recent rise in the British Columbia tax on the output of metalliferous mines in that province.

THE water-jacket smelting furnace is mentioned and illustrated in "Overman's Metallurgy," published fifty years ago.

GEORGIA gold miners in convention at Atlanta this week organized the Southern Gold Miners' Association. They want concentrators and chlorination.

IN estimating the quantity of water required for steam making in boilers, seven and one-half gallons per hour per horse power is generally figured as correct.

ALLISON RANCH, Grass Valley, Cal., miners objected to go to work one night last week by reason of the alleged presence of a ghost therein. Most miners have seen too many ghosts to believe in them.

AN attempt is being made in southern Oregon to smelt ores on a commercial scale by the use of oxygen and hydrogen gases with carbon generated from crude petroleum. It is, in fact, a huge oxy-hydrogen blowpipe.

IF 500 gallons of water can be pressed through a 6-inch pipe per minute, with a head of 40 feet, the length of a 12-inch pipe to pass the same quantity of water per minute with the same head of pressure should be 32 feet.

THE steamer Alameda, at San Francisco this week from Sydney, reports the finding of a gold nugget in Western Australia weighing twenty and a half pounds in February, twenty miles from Marble bar, in the Pilbarra gold field.

SOMETHING new in "stamp mill practice" is reported from Baker City, Or., where the municipality will supply the adjacent stamp mills with water at a regular stated price.

THE specific gravity of quicksilver is 13.6 at 32° F. It evaporates slightly at ordinary temperature, melts at minus 39° F. and boils at 680° F. The melting point of gold is 1915°; that of silver 1750°; of copper 1930°; of cast iron 2500°; of lead 625° F.

TO FILL holes in castings take one part gum arabic, one part plaster and one part iron filings and mix with a little water. Some metals expand in cooling when alloyed with other metals, as lead 75 parts; antimony 16.7 parts; bismuth 8.3 parts.

AMALGAM plates may be cleaned very closely by pouring a quantity of scalding hot water over them for some time. This process is known as sweating and should only be employed at long intervals or when shutting a mill down for an indefinite time.

TO FIND the diameter of a pump cylinder to move a given quantity of water per minute (piston speed being 100 feet per minute), divide the number of gallons by 4, then extract the square root, and the result will be the diameter in inches very nearly.

METAL mines are not ordinarily troubled with fire damp, though there are exceptions. In the Abbott quicksilver mine, Lake Co., Cal., this explosive gas occurs in considerable abundance. It is fired frequently to prevent an accumulation of a large body of gas.

THERE is no limit to the number of mining claims that can be taken up in the name of a man, woman, minor or corporation, provided he, she or it can do the annual work necessary to hold them or make would-be relocators believe that such work was done.

WHERE Smith locates a placer claim, pure and simple, without reference to any lode claims thereon, Brown can locate and hold a lode claim, if he can find one, within the limits of Smith's claim, any time before Smith has received a U. S. patent to his placer claim.

DRILLS for hard granite or greenstone should be tempered light yellow to straw color. Too light is too hard, and darker than straw color is too soft. Care must be taken at all stages not to overheat the steel. A dark blue is a suitable temper for picks for most uses.

RESIDENTS of that vicinity prophecy a repetition of the formation of the Salton sea, as in '67 and '92, because of the presence of from 16 to 40 feet of snow on the headwaters of the Colorado river, which, if rapidly melted, would flood the Needles, Cal., and adjacent country.

A STEEL rope having a hempen core is more durable than one having a steel core for the reason that the strands about a steel core are bent and cut more or less by pressing on the steel core when bent over sheaves and the drums of hoisting engines. The hempen core being soft obviates this difficulty.

THE dividends declared by the Cripple Creek, Colorado, mines during February exceeds all previous records, aggregating $378,000, an increase of $176,000 compared with the January disbursements. The gold output was $1,257,250, a decrease of $500,000 compared with January, this being due to the unusual snowfall.

THE jury trial of F. L. Girom at Baker City, Or., resulted in acquittal. E. Imhaus, agent for the French company which paid defendant $20,000 for a mining property, claimed that the mine had been "salted." It was a case of buying a mine by sample. The samples assayed well. Indeed, Mr. Imhaus testified that in the aforesaid samples gold was visible to the nude eye. While the company is out $20,000, yet it saved the few hundred dollars that an expert report would have cost.

GOLD may be precipitated from bromine solutions containing gold by sulphuretted hydrogen, in the form of dark brown powder. The bromide process for treating gold ores is a chemical success, but has not been adopted because of the expense. A laboratory process is often satisfactory, when as a commercial proposition it would not produce good financial results.

ON the Comstock, at the time sinking was discontinued, the "combination shaft" of the C. & C. had reached the vertical depth of 3250 feet. There was then (March 28th, '82) only one deeper shaft anywhere—the Adalbert, Bohemia, 3280 feet. Now there are several deeper in this country, the Calumet & Hecla, Lake Superior district, being nearly 5000 feet deep.

THE latest in big sulphur deals is reported from the City of Mexico to the effect that C. S. Ocha has closed a deal for the sale of Popocatapetl to English capitalists for $250,000 in gold. An extensive sulphur deposit is located in the crater of the volcano, and it is the reported intention "to build a cog-wheel railroad to the top of the mountain in order to handle the product."

THE report of the Canada Geological Survey shows that in '98 there was an increase of over $9,000,000, or nearly 32%, in the production of minerals in Canada as compared with '97. In the more important mineral products the increases were as follows: Gold, $784,000; coal, $924,000; copper, $658,000; nickel, $422,000. The increase in Ontario was over 50%; the total value of metals produced was $21,622,601.

A RULE for finding the required length of belts is as follows: Add together the diameter of the two pulleys, multiply by 3⅛ and divide the product by 2; add to this twice the distance between the center of the shafts and the product will equal the length of belt required. The horse power of a belt may be found by multiplying its velocity in feet per minute by its width in inches and dividing by 1000.

TO FIND the capacity of a pump in gallons, square the diameter of the piston or plunger in inches, and multiply by .0034, which will give the number of gallons for each inch of stroke; then multiply by the length of the stroke in inches to get the number of gallons displaced at each stroke. This amount, multiplied by the number of strokes per minute, will give the quantity of water elevated by the pump in one minute.

AS ELSEWHERE, electrolysis in San Francisco has occasioned considerable injury to gas and water pipes. The pipe so destroyed by return currents from adjacent electric railways is usually in the vicinity of power houses, and is honeycombed with holes, being rendered useless. The current is particularly destructive to lead pipe. In thoroughly constructed electric railways provision is made for proper conveyance of the return current.

IN parts of California there will be a lack of water this season for mining purposes; the great area of the State and its topography fortunately makes a general drought impossible, though to those needing the usual water supply State lines afford no relief. With an axial line equaling in extent similar Atlantic area from Massachusetts to Georgia, it is not unusual to find floods and droughts and other eccentricities as on the sunrise slope of the continent.

ANSWERING Riverside, Cal., and Georgetown, Colo.: A grain equals 0.0648 gram; an avoirdupois ounce equals 28.3495 grams; a troy ounce equals 31.103 grams; a pound equals 453.59 grams; a milligram equals 0.015 of a grain. The "unit of weighing" in the metric system is the gram, which equals 15.432 grains. A kilogram of wolframite (or anything else measured by weight) is 1000 grams, or 2.204 pounds; powdered and 96% fine, that quantity is worth $2.38 in Germany.

IN stating last week that an assay ton contained 480 grains, "Concentrates" erred. The assay ton, which is the unit of the system, contains 29.166 grams. One pound avoirdupois contains 7000 grains; 2000 pounds = 1 ton. 2000 × 7000=14,000,000 troy grains in one ton avoirdupois. 480 troy grains = 1 ounce troy. 14,000,000 ÷ 480=29,166+ troy ounces in 2000 pounds avoirdupois. There are 29,166 milligrams in 1 assay ton, hence 2000 pounds is to 1 assay ton as 1 ounce troy is to 1 milligram.

F. A. PLENKER, Grangeville, Idaho, is an uncommonly good prospector or else is exaggerating facts when he states that he recently made a big discovery of a ledge of gold quartz. He says that "after looking around for a likely place to dig he sank through the snow 10 feet," and soon beneath the surface of the earth, about 18 feet from the snow level, found what he was looking for. It is fortunate the snow was only 10 feet deep. Had it been 11, he might have had difficulty in accurately determining just where to dig.

ONE of the greatest evidences of Colorado's mineral wealth and prominence is the recent contest in the Colorado Legislature over the proposed creation of Teller county, as a Cripple Creek expansion proposition. The speeches, charges, bribes, allegations, etc., were the sensation of the session, being to Colorado what the lofty Senatorial contest has been to California, Montana, Utah and other great commonwealths where the best man is always sent to the U. S. Senate, neither wealth nor unworthy influence cutting any figure in such noble selection.

STATE Legislatures are busy over mining matters. In Colorado the Assembly has passed a bill prohibiting the consummation of a smelter and mining trust. In Montana the Legislature passed a law admitting the creation of a copper combine: the Governor vetoed it, and the Legislature passed it over his veto. Utah and Arizona have passed new bills looking to the interests of the miner and prospector; California again endorsed the Mineral Land bill, but Speaker Reed was again successful in the National Legislature in preventing the passage of that necessary measure.

"CONCENTRATES" was mistaken in the issue of the 4th inst., in an item on the first use in California and Colorado of electricity in mining, in saying: "The first time electricity was used for mining in California was in Placer county, in '89." Dr. N. S. Keith, the pioneer in many of these things, finds that the first mining electric power transmission plant in California, as described and illustrated in detail in the issue of the MINING AND SCIENTIFIC PRESS of Jan. 28th, '92, was a Brush dynamo, at Placerville, El Dorado Co., for the American River Syndicate, at the Dalmatia mill, May 19th, '90. So that it was at Placerville, and not in Placer county, that the first operation of that kind in California began.

IN California, Colorado and Utah electricity occupies a prominent place in mining operations, and its use is extending. In Montana, the new electrical plant, sixteen miles from Helena, just installed, gives promise of permanent reduction of cost charges in working the thirty miles of porphyry dike in that vicinity. It is locally calculated that the cost of treating the low-grade ore there can now be reduced from $2 a ton to 75 cents. The company figures on ultimately extending its lines forty miles to Butte. The idea is feasible. In southern California a 40,000 voltage is now transmitted eighty miles, and another California concern is preparing to transmit a 33,000 voltage 125 miles.

MODERN COMFORT, modern progress, the achievements of science, the daily requirements of every line of business, all depend upon the mining industry, which is the greatest factor in the industrial development of the nation. Nothing has done more for the country; nothing has had less recognition. The mining industry has developed this west half of America, has furnished the sinews of war and the requirements of peace, and its trials and successes rival the greatest of any other of the world's achievements. The mining industry is entitled to representation in the presidential cabinet, not as a favor or a fostering care, but as a matter of business, a necessary present demand, a measure of justice to the general public, whose needs could be better conserved thereby.

THE following (Sec. 2333, Revised Statutes of the United States) serves to completely answer several questions this week: Where the same person, association or corporation is in possession of a placer claim, and also a vein or lode included within the boundaries thereof, application shall be made for a patent for the placer claim, with the statement that it includes such vein or lode, and in such case a patent shall issue for the placer claim, subject to the provisions of this chapter, including such vein or lode, upon the payment of $5 per acre for such vein or lode claim, and 25 feet of surface on each side thereof. The remainder of the placer claim, or any placer claim not embracing any vein or lode claim, shall be paid for at the rate of $2 50 per acre, together with all costs of proceedings; and where a vein or lode, such as is described in Sec. 2320, is known to exist within the boundaries of a placer claim, an application for a patent for such placer claim which does not include an application for the vein or lode claim shall be construed as a conclusive declaration that the claimant of the placer claim has no right of possesion of the vein or lode claim; but where the existence of a vein or lode in a placer claim is not known, a patent for the placer shall convey all valuable mineral and other deposits within the boundaries thereof.

THE sale by H. R. Wolcott of the property of the Colorado Smelting & Mining Co., at Butte, Mont., for $2,500,000, is understood to definitely indicate the consolidation of numerous smelter interests, and that the new trust is the buyer of the Butte property. It is understood that the property of the Pennsylvania Lead Co., at Pittsburg, and the Pennsylvania Smelting Works at Salt Lake City, Utah, are also included in the deal, and it is reported that the officers of the new $65,000,000-combine will be elected April 1st. The following firms are said to be in the combine: The Omaha & Grant Smelting Co., with works at Omaha, Denver and Durango, Colo.; the Con. Smelting & Refining Co. of Kansas City, Mo., with works at Kansas City, Leadville, Colo., and El Paso, Tex.; the United States Smelting & Refining Co. of Chicago, with works at Chicago, Pueblo, Colo., Helena and Great Falls, Mont.; the Aurora Smelting & Refining Co., with works at Aurora, Ill.; the Pueblo Smelting & Refining Co., with works at Pueblo, Colo.; the Philadelphia Smelting & Refining Co., with works at Pueblo, Colo.; the Globe Smelting & Refining Co., with works at Denver, Colo.; the Germania Smelting & Refining Co., with works at Salt Lake City, Utah; the Bimetallic Smelting Co., with works at Leadville, Colo.; the Pennsylvania Smelting Co., Salt Lake City, Utah, and the Pennsylvania Lead Co. of Pittsburg, Pa. The combination incorporates at Trenton, N. J., under the name of the Consolidated Smelting & Refining Co. It is understood that the property at Butte, sold for $2,500,000, is of same company organized in 1880 by Colorado men, who put $100,000 into the enterprise, which amount has been paid back to the stockholders in dividends, and who now get twenty-five times what they originally put in.

ANSWERING practically the same question from Columbia, Cal., Gunnison, Colo., Harqua Hala, Arizona, and Bingham, Utah, it has been held by the Utah Supreme Court that where one or more locate a claim and fail to do required annual assessment work, any one of the former locators can relocate the claim, when it becomes subject to relocation, and by complying with all federal and local requirements can in law hold it. Such decision was subsequently appealed from to the Supreme Court of the U. S. At one time the acting commissioner of the General Land Office held that one of three locators, whose claims had lapsed, could relocate and hold the location against his former partners provided he complied with all the requirements. Both the Utah decision and the acting commissioner's ruling seem very shaky, and not in accord with even the letter of the law, much less its spirit. The law is very liberal, and if a man or men be permitted to take advantage of their own intentional failure or unintentional neglect, it would seem to be putting a premium on evasion and tending to perpetuate a wrong. The Supreme Court of California has held in a case of this kind that if the work prescribed in the federal act be not done the claim is open to relocation "unless work is resumed before the second location is made." If it be finally decided or admitted that the original locator is to be allowed to relocate as a sort of reward for his own neglect, it will result in an added inducement to further evasion of the liberal federal law. That law says that if a man or men locate a mining claim or claims, say today, March 11th, '99, he or they shall have till midnight, Dec. 31st, 1900, to put thereon the required amount of labor or improvements, and not till the latter date named shall noncompliance with the requirement regarding such work be deemed a failure, and that in case of such failure the claim or mine upon which such failure occurs shall be open to relocation in the same manner as if no location of the same had ever been made; provided, that the original locators or their heirs, assigns, or legal representatives, have not resumed work upon the claim after failure and before such location.

A Boston, Mass., Electric Power Station.

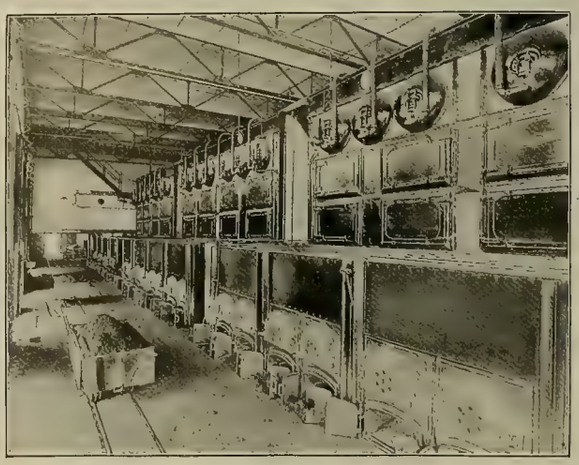
The latest of Boston's seven power stations installed is one on the Charles river, called the Harvard, which in its arrangement deserves illustrated notice. The station is designed for an ultimate capacity of 7200 K.W.; the present building is constructed to contain four units of 1200 K.W. each, three of which are installed. The building is 171x125 feet.

An illustration of the boiler room shows the full width of the building, 56 feet. Six boilers are installed in three batteries, with alleyways on each side and in the rear. Each boiler has a nominal capacity of 500 H. P., three water drums of open hearth steel, 60,000 pounds tensile strength, 42 inches in diameter, 22 feet long, the front end projecting through the setting. The boilers are double-decked, each deck consisting of twenty-one sections, each six tubes high, making 252 18-foot, 4-inch tubes in each boiler, with a total heating surface of 5124 square feet. The drums are protected by 4-inch pop safety valves, set to blow off at a pressure of 175 pounds to the square inch. The coal bins have a capacity of 750 tons and are provided with an inclined track running up from the street level and carried on trestle work round a loop and back over the top of the bins. The coal handling is done entirely by machinery up to the furnace door.

The gases from each boiler are passed into the chimney through a fuel economizer of fifty-six sections, each containing ten tubes and aggregating 6720 square feet of heating surface. The chimney is 226 feet high and has an inside diameter of 11 feet.

The engine room, illustrated herewith, is on the north side, 170 x 66 feet.

The basement floor is on a level with the boiler room and contains the pumps, condensers and heaters. The three vertical triplex power pumps, 6 inches in diameter by 8 inches stroke, are driven by belts and shafting from a 500-volt electric motor, and, being operated electrically, can be used to feed the boilers when steam is not available. There is also one duplex steam pump 14 inches by 8 5 inches by 10 inches stroke. Openings are left in the engine



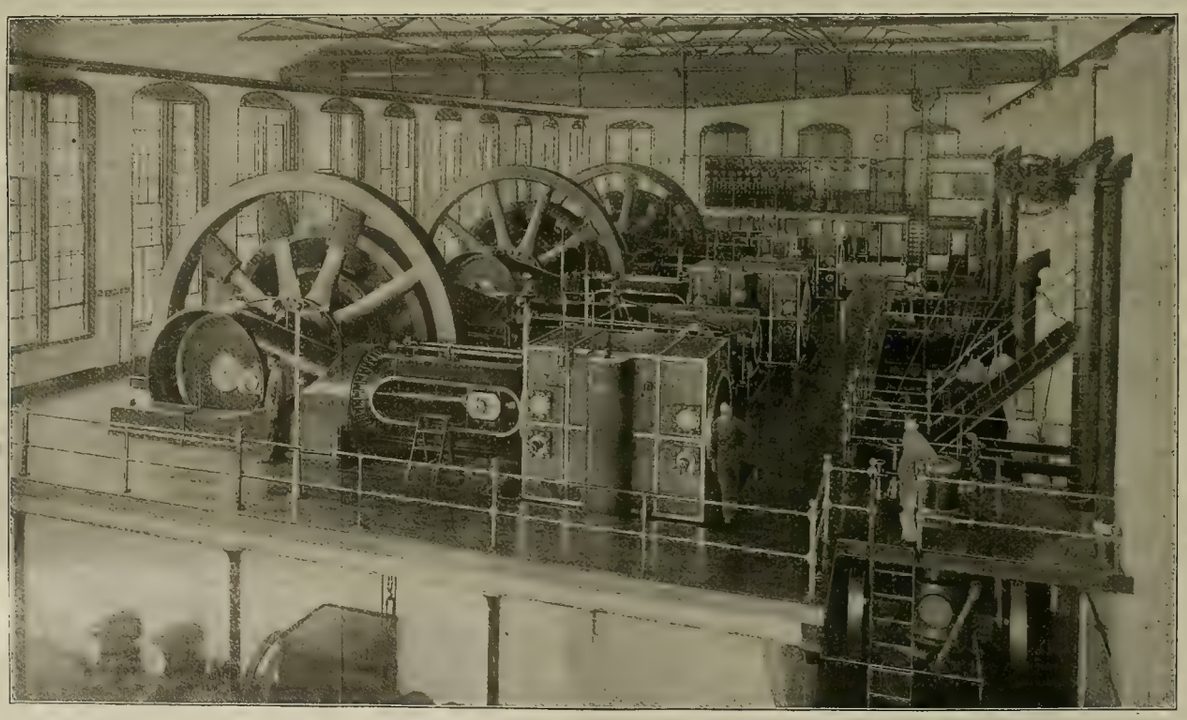
BOILER-ROOM OF THE HARVARD POWER STATION.

room floor to permit of the pumps and condensers being seen at all times by the engineers on duty, and are properly guarded by railings.

The engines are of the horizontal, cross-compound, condensing Corliss type, and are direct connected to the generators. The cylinders are 28 and 56 inches in diameter, with a 60-inch stroke, and are designed to run eighty revolutions per minute. The flywheels are 24 feet in diameter, built up in segments rigidly bolted together, and weighing about sixty tons. A reheater or receiver is placed between each of the high and low-pressure cylinders, and each cylinder may be run alone or run condensing or non-condensing by a suitable arrangement of the piping, which is all below the engine room floor. The main steam pipe is 14 inches in diameter, with 8-inch connections from each boiler.

Three direct-connected, twelve-pole, compound-wound generators have a capacity of 1200 K.W. each. The frames and pole pieces are cast steel; each field spool is arranged with separate spaces for the shunt and series windings. The series coils are wound with flat strips of copper; the shunt coils are composed of the usual round insulated copper wire.

The armatures are built up of laminated discs of soft iron, dovetailed into a spider and held securely in place by large cast iron rings bolted tightly together. Each frame rests on two foundation plates bolted down on the capstones. The switchboard is composed of thirteen feeder panels, three generator panels and one station panel. Each feeder panel carries two feeders and the necessary ammeters, switches and circuit breakers. Each generator panel has a 5000-ampere circuit breaker and ammeter, a 3000-ampere, double-pole switch and the field rheostat controller. A recording watt meter is provided, by which an account of the output of the station is kept. A recording voltmeter and recording steam gauge are installed in the office, keeping record of the voltage and steam pressure for reference. All the feeders from the station are carried underground in conduits. This station is connected with five other power stations, enabling the load to be distributed, in any manner, among the various stations, according to their capacity.



ENGINE-ROOM OF THE HARVARD POWER STATION, BOSTON, MASS.

Wave Vibrations.

F. W. Branson, as a result of recent experiments with sound waves and with the Hertzian waves to illustrate the dissimilarity of the radiations of the atmosphere and of the ether, gives the gradations which may be observed between sound, light, heat and electrical waves as follows:

Vibrations per second.

288,224,000,000,000,000	Roentgen rays.
1,125,899,906,842,624	Photographic limit of solar spectrum.
562,949,953,421,312	Green light.
281,474 976,710,656	Infra red.
70,368,744,177,664	Heat rays of solar spectrum.
67,108,864	Electric oscillations in Hertz resonator.
32,768	Audible vibration.
4,096	Music, highest note.
32	Music, lowest note.
16	Water surface waves of minimum velocity.

Some Experiences of a Working Miner.

NUMBER V.

Written for the MINING AND SCIENTIFIC PRESS.

Not all the mines I have visited are operated to their disadvantage, as might be assumed from reading the previous papers of this series of letters. Take, for instance, the G. G. mine. At the surface a small free-milling vein, it was equipped with small plant and under careful management slowly developed into a larger mine, with increasing value as development proceeded, and to the credit of the management it can be said that the work of exploration was always in advance of stoping. In time it became evident that the condition of the property justified a larger mill and an addition was made doubling its capacity. Still later a larger hoisting plant was deemed necessary and the addition was made at considerable expense, the mine paying for this and all other improvements. The mine is still working successfully and is thoroughly equipped in every department and is one of the best examples of legitimate mining in California.

In contrast with this look at the P—— mine. A deep shaft was planned, an expensive hoisting plant installed and everything was carried on with a rush. When the shaft was 300 feet deep, without a pound of ore in sight, a 40-stamp mill was rushed to completion under a sixty days contract, the men working night and day. The mill never dropped a stamp. Work in the shaft was stopped and the machinery was eventually moved elsewhere.

In its early history the H—— mine was a great producer. It was worked steadily and profitably for years, but at last the end came and the mine was shut down. After an idleness of many years M—— secured a bond on the property, and started in to rehabilitate it. A new dam was constructed in the river, a flume and ditch built, the air compressors removed to a new site, fifteen stamps of the mill were reset, the tramway relaid, buildings overhauled and the whole proposition on the surface gotten into good shape. Then work in the mine was recommenced. The shaft was pumped out and everyone expected to see sinking and systematic development begin, but in place of that all energies were directed to the recovery of old pillars standing in the mine, the faces of old stopes were cut into and every effort made to make a new mine out of one which had not only been carefully worked, but gouged to the last dollar's worth of ore. The natural result followed. The mine was closed down when the money was gone, and it stands idle to-day, though well-directed effort may make it again a paying mine. Had the money spent in rebuilding the mill and stoping worthless quartz been put into sensible development, it is my belief that the mine might possibly be in operation to-day.

A long crosscut tunnel was driven in the F—— mine, and considerable development done on the vein, but owing to the all but inaccessible location of the mine, it was shut down when the backs had been stoped out. A few years later it was deter-

mined to reopen the mine. The crosscut tunnel nearly 500 feet in length was found caved. One of the miners who had worked there in former days was in charge of the work. He asserted positively that he knew the ground thoroughly and in his opinion it was caved its entire length, and therefore it would be cheaper to drive a new tunnel than to reopen the old one and keep it open. Accordingly a new tunnel was driven and the vein reached. When the new crosscut entered the old workings the men explored the place to ascertain the condition of things. When they came to the old crosscut it was open so they walked into it to see how far it had caved. They walked out 450 feet toward the mouth. Only 50 feet was caved. The F—— mine had good ventilation now by reason of its two tunnels.

When the shaft in the G—— B—— mine had reached a depth of 300 feet, with levels run several hundred feet at 100 and 200, the vein was found intact throughout with a fine ore shoot which "feathered out" on all its edges. This shoot occurred in a broad crevice 4 to 20 feet wide. There was not a crosscut in the mine. The owners gave up the mine as not offering sufficient inducement under the circumstances to continue its development. Subsequent owners have deepened the shaft, crosscut the fissure and have developed a valuable mine, it having been found that the ore shoots reoccurred in depth, appearing as a succession of lenses. The fact demonstrates the necessity of crosscutting in soft fissures where well-defined ore shoots pinch out.

MINER.

That those who read these experiences of the writer may appreciate that they are not in the least overdrawn, being rather understated than exaggerated, the following letter written by a miner who evidently was at the mine referred to at a later period, is given as corroborative evidence:

"'Miner' has failed to do full justice to the transportation situation on Cedros Island. Take as an example the ore from a lower stope reached through Michaelson No. 2 tunnel: Hoisted 20 feet by hand; sacked; wheeled in barrows to mouth of tunnel; stacked; packed in burros to chute; stacked; chuted to platform over car of gravity tram; stacked; trammed one-quarter of a mile to end of wagon road; stacked; transported by wagon two and one-half miles to wharf and stacked. From there your correspondent has it correct. The average assay of this particular stope was $12.50. The ore was base and unsuited for milling." ANOTHER MINER.

Hedges, Cal., March 3rd, '99.

The Smelting of Ore in the Kootenays.*

It is now announced that the Canadian Pacific Railway Co. will commence, during the coming spring, the construction of a large reduction plant in the Boundary region. This scheme is in the line of the general policy of the company, as already outlined, namely, to give the miners in this section of British Columbia the benefit of the lowest possible smelting charges on all classes of ores, thus placing them, as regards the cost of reduction, upon the same footing with the miners of the older camps in the United States. At Trail, this has been already accomplished by the establishment of charges of $7 per ton (and, in some cases, even less) for the treatment of refractory ores, requiring roasting, and containing a high percentage of silica and alumina, while running very low in copper. It may be doubted whether more favorable rates are offered to miners of such ores even in Colorado or Montana.

The policy of building large smelters, which seems to have been adopted and to be in process of energetic execution by the Canadian Pacific Railway Co., with the aid of first-class metallurgical ability in the details of design and operation, has been sometimes criticised as detrimental to the general development of the smelting industry, and thus, indirectly, of the mining industry as well, in the Dominion. It is argued, sometimes, that the entrance into this field of a large corporation, controlling the business and rates of transportation, discourages private smelting enterprises, and thus deprives the miner of the advantages of free competition, such as is supposed to be prevalent in the United States. This is a plausible theory; and it is conceivable that, under certain circumstances, it might be confirmed in practice. For instance, if a large railway corporation, having excluded rivals from the field, should proceed to extort unreasonable profits from an industry at its mercy, there might be reason for complaint. But the remedy of such an evil lies in the nature of the case, even apart from legislative interference as to rates. A simple consideration of the amount of capital invested in a great railroad, as compared with that invested in a smelting works, or a dozen smelting works, will show that the transportation business is far more important than the contributory smelting business, and that no great railroad company can afford to restrict its transportation of ores, bullion and supplies by imposing high rates upon its customers in the comparatively subordinate business of smelting. If the smelting business should be owned by a favored "ring," which sacrificed to its special interest the interest of the railway company, the case, it must be confessed, would present a different aspect. But that evil has its own appropriate remedies; and, as it is not indicated in the situation now under consideration, it need not be considered here.

The general proposition as to the comparative benefit to the mining industry of a few large smelting works, located at suitable commercial centers, and numerous small works, located close to the mines, has been abundantly illustrated in the United States. All through Colorado, Montana and Utah are scattered the ruins of abandoned smelting works, which have been operated from a day to a year, it being only a question of time how long they could survive. Not one of them ever reduces ore cheaply. Without exception they have failed, in spite of high smelting charges, because such small concerns, located with reference to an adjacent ore supply only, without regard to the larger controlling conditions of success, could not possibly succeed. Only in a very few instances, such as the United Verde, the Anaconda and the Calumet & Hecla copper mines, or the great New Jersey zinc mines near New York City, can a single deposit or locality support its own reduction works and furnish them with ore mixtures adapted to economical reduction.

There is a stage in the development of every new mining region, in which the local rivalry of competing camps demands that each shall have its own "smelter," as an evidence of its permanent progress, and often goes so far as to offer "inducements" to capital, on the strength of which it may, perhaps, undertake the perilous venture. The (usually both ill-advised and inadequate) investment of capital on such conditions speedily comes to grief; and at last it is generally recognized that large smelting works, located at points where fuel, fluxes and ores can be economically assembled and scientifically mixed for the best metallurgical results, and able (by means of their size) to employ the best metallurgical talent, offer to the miner the highest rewards for his labor. Even in instances where small local establishments profess to offer better terms, there is the not uncommon risk that they may "get even" by various tricks of the trade, to which large concerns cannot afford to descend.

In short, the so-called "competition" of small local smelters is a matter which larger concerns in the United States have learned to despise and disregard, knowing that it must die from its own inherent impotence.

Meanwhile, it is a pertinent question: What is the effect of such temporary competition upon the mining industry itself? A small local concern may, for a while, by virtue of the ignorance of its management and the credulity or optimism of its shareholders, go on, in competition with larger, better located and better managed establishments, offering rates which it cannot afford to pay, and losing money without knowing it. There is scarcely any other business in which so great losses can be unconsciously incurred as in that of smelting. The periodical balance sheet is largely an estimate on paper. Values supposed to be contained in ores and by-products on hand are credited as assets, and nothing but an absolute and complete cleanup will demonstrate the actual situation. The management may go on, using up its working capital, for many months after real business failure has been experienced. During such a period individual ore sellers may receive, on individual lots often, prices higher than could fairly be paid; but the permanent interest of the mining industry has been really injured, and when the collapse comes the reaction is likely to more than outweigh the temporary gain.

In a word, the waste incurred by the crude and unskillful smelting of ores in small local works is absolute waste, which does no good to anybody. The saving effected by skillful treatment, under favorable conditions, in properly located large works, is an absolute saving, which involves no loss to anybody, and is large enough to give both higher prices to the miner and fair profits to the smelter. Consequently the latter system is more advantageous to both parties, and anything which hinders or delays its adoption is injurious to both.

* Canadian Mining Review.

A Long Canoe Trip.

On May 1st two men will leave Vancouver, B. C., on an unique trip across the continent. From the headwaters of the Fraser river to the source of the Bow river is only six miles, and there is a complete water route to the eastward. The men who will go across the continent in a canoe are A. J. Clark and T. A. Smith. They figure they will travel 5000 miles, visiting over 1000 towns and cities. A long, slender canvas canoe, weighing ninety pounds, will be the means of transportation. "We will make our journey up the Fraser to Banff," says Clark, "and then go down the Bow river to Saskatchewan. Then we go into Thunder creek, and finally reach the Qu'Appelle river. Next we come to the Asinaboine river, and this takes us to Winnipeg. Then we will go by way of St. Paul through rivers, canals and lakes to Washington, D. C."

Crushing Rolls.*

The reduction or granulation of coarse particles of ore by means of rolls, has been given much consideration during the past few years. The variety of crushing rolls are many and various in type and construction. Machines for this class of work have largely been evolved by American engineers, and proof of their superiority is to be found in the fact of their having gained admission to almost every large metallurgical works throughout the world. Notwithstanding the many changes that have been made during past years in all the various designs known to us, no special one has met with general approval. The most potent change has been in the adoption of steel as the material for use in the construction of the shells. The construction of the frame in one piece, having sufficient weight and strength to absorb the vibrations set up within the machine, and closer study has been given to the matter of the strains with the structure. Marked improvement over the older forms of crushing rolls has been made in the design of journal bearings, methods of lubrication, and the facilities for dismantling the machine if required.

Considerable ingenuity has been displayed to obtain complete and satisfactory methods for keeping the lateral adjustment of the rolls correct. The adoption of springs for that of levers and dead weights within the machine, to give crushing power to the rolls, is an important improvement, affording, as it does, a much more uniform product. The adoption of some form of housing obviates the wasteful and disagreeable nuisance of dust, usually found around rolls employed in dry crushing, and length of life to the machine is ensured.

The most marked change within recent years has been along the line of increased peripheral speed by the employment of rolls of larger diameters and narrower faces, the results being decrease of journal friction, increase of crushing surface, and reduction of spring pressures. Those changes are undoubtedly the direction in which modern practice is tending.

Peripheral speeds of 600 to 1000 feet per minute are now found to be practicable, but this change in speed has also brought about many of the improvements already mentioned. The aggregate spring pressure is now greater, ranging from two to three tons per inch width of face of roll shells. Change has also been made from gears to belts, proving a much more preferable method of driving.

In the earlier form of rolls the spring pressure was carried along the main tension bolts, making it a matter of considerable labor to adjust the rolls. The method now in use consists of enclosing the whole nest of springs between two washers, and constructing them so that each nest forms a complete washer, of an inelastic nature, until such time when the maximum pressure is reached, further compression taking place, relief is afforded to the rolls by the deflection of the springs.

Chilled iron shells in all probability will be displaced by steel shells. In the design of rolls presented all the above mentioned improvements have been embodied, simplicity of construction, fewness of parts, and interchange ability is to be found. The hopper underneath the rolls is constructed in such a manner that no pockets are permitted, all four sides declining towards the bottom at an angle of 45°, thus affording cleanliness at all times within the machine. The matter of sliding versus swing bearings for the removable roll, was decided in favor of swinging roll bearings. The wearing surfaces become reduced by means of their adoption. Any wear about the bearing surfaces of sliding roll bearings is an evil, which may result in damage to the frame of the machine; it is easier to maintain the alignment of the swinging bearing than in the sliding type of bearing.

In design for rolls, a feature worthy of consideration is that of the disposition of the bolts employed for the purpose of bolting the machine together, it is a desirable feature to have as few as possible, and so arranged that should they by any means become loose, they may not fall within the machine. The use of common nuts is not desirable, and recourse must be made to lock nuts or elastic nuts; this provision prevents the bolts becoming loose, and may help to preserve the machine from injury.

*A. C. McCallum before Canadian Inst. M. E., Mar. 2.

FROM experiments lately conducted at one of the Reichanstalten in Germany, on nickel-iron alloys, it has been developed that the coefficient of expansion of such alloys varies according to the percentages of the two metals present. Furthermore, it is said to have been experimentally demonstrated that an alloy of iron and nickel containing 45% of nickel possesses the same rate of expansion as platinum, and it is proposed to use this alloy to replace platinum in the manufacture of incandescent electric lamps.

A Mine Beyond the Arctic Circle.

When the British Iron and Steel Institute met in Stockholm, Sweden, last year, the Aktiebolaget Gellivare Malmfaelt invited some of the members to go on an excursion to the mines at Gellivare, Malmberget, etc. The greatest deposits are in the province of Norrbotten, Lapland, communication being by rail from Lulea, a port on the Gulf of Bothnia. This port is closed by ice for seven months of the year, so it is proposed to extend the line to Victoriahaven on Ofoten Fiord in Norway, which is open all the year round. The Gellivare deposits lie forty-three miles north of the Arctic Circle, and have been known since 1704, being referred to in a report of that year. The first concession for working them appears to be that of Lieut. Tingvall, 1735, who turned his rights over to a company in 1742, but the mining business did not thrive, as transportation facilities were very inadequate, and for many years there was but little business done there. In 1888 the railroad was completed from Lulea, a distance of 130 miles, and in 1892 there were shipped 139,194 tons of ore. Since this year the shipments have shown a steady growth, as the following figures will exhibit: Shipments to Lulea of Gellivare ores: 1892, 139,194 tons; 1893, 260,754; 1894, 525,728; 1895, 384,007; 1896, 614,262; 1897, 815,797; 1898, 804,732. The mine is described by D. A Louis in the *Engineering Magazine*.

The ore is for the most part magnetite, although hematite is also present. At the King Oscar mine, one of the largest in the district, the ore deposit on the outcrop is 670 feet long and from 27 to 337 feet wide, having a total area of 21,600 square yards. The system of working here, as indeed throughout the district generally, is by open-cast, bench work, and the ore is graded, according to its content of phosphorus, into five sorts, the phosphorus varying from below 0 05% to above 1.50%. Mr. Louis says that Grade E, having above 1.50% of phosphorus and some sulphur, is heated in order to separate the magnetite and hematite from the apatite. The magnetite is separated over magnetic separators, while the hematite is separated from the apatite by means of jigs, riddles, and shaking tables. The fine ore is troublesome, and no means of disposing of it have been found as yet. The apatite, mixed with some quartz and feldspar, is dried, ground, and mixed with salt cake, and fritted into a mass which has a ready sale as a fertilizing material. Two hundred tons of ore are treated per dav, and the yield of this Wiborgh fertilizer is from 1% to 1.50% of the ore. The fertilizer is worth about $19 a ton.

The mines employ about 1500 men during the winter and 2000 during the summer. Considering the high latitude, nearly 68°, the temperature, even during the coldest part of the winter, is seldom lower than 20° below zero, and the snow and frost do not interfere with the working of the mines. The power for the various operations is supplied by three 120 H. P. and one 360 H. P. compound condensing engines coupled to dynamos. There are 130 arc lamps, 500 incandescent lamps, and sixteen motors in use. Mr. Louis does not quote any analyses, but it is known that the Gellivare magnetite used at Witkowitz carries from 61% to 64% of iron. There is a grade of Gellivare ore that carries about 69% of iron, but for the most part the ore carries from 60% to 65%. It is transported 1680 miles to the Cleveland district, England, and 1690 miles to Dortmund, and 1400 miles to Witkowitz, the distances being taken as an indication of the richness of the ore. These deposits are very large, and are worked with comparative cheapness, so much so, in fact, that the best grade ore is sold at Middlesborough for $4.50 per ton.

British Columbia Mining Requirements.

The following is a summary of the provisions of the Act passed during the recent session of the British Columbia Parliament, amending the Inspection of Metalliferous Mines Act. Among other things it provides that it shall be the duty of the inspector, in case a mine is in a dangerous state, to post up in a conspicuous place at the mouth a notice warning the workmen. Further, owners must give notice of any serious accident, and no person may be employed underground for more than eight hours in the twenty-four. Explosives must not be thawed underground in any mine. Following are other important sections:

Any adjoining owner may apply to the inspector for the purpose of learning whether such mine is being worked into his territory, and upon such application being made the inspector shall examine the plans of such mine, and if necessary examine the workings of such mine, and make report thereon to such adjoining owner as to whether his territory is or is not being encroached on.

Not less than 75 cubic feet of air per minute shall be made to pass through every mine for each man and beast employed therein.

All permanent buildings for housing boilers, engines and machinery shall be erected at a distance of not less than 50 feet from the mouth of any mine.

Slides, or conductors, for shafts which are at least 100 feet deep shall either be iron shod or all iron.

All vertical shafts of a depth of at least 50 feet shall be provided with a crosshead and guide, and such crosshead shall descend as such shaft is sunk, so that at no time shall it be at a greater distance from the bottom of the shaft than 30 feet.

No stope or drift shall be carried on in any shaft which shall have attained a depth of 200 feet unless suitable provision shall have been made for the protection of workmen engaged therein, by the construction of a bulkhead of sufficient strength or by leaving at least 15 feet of solid ground between said stope or drift and the workmen engaged in the bottom of such shaft.

A chain ladder 20 feet in length shall extend from the bottom of the wooden ladder to the bottom of the shaft.

An Automatic Accountant.

The latest thing a machine does is to "keep books." Such concerns are now in use in New York City. One in the Union Savings Bank is operated by electricity. It marks in a depositor's book the amount of his deposit, and makes a duplicate of the entry on a tape locked in a box attached to the machine. At the same time the amount of the deposit is automatically added to the total of the bank's transactions, so that a glance at the latter would tell just how much money the bank had received since its organization.

The machine is placed on a table at the teller's right hand. In front of it is a keyboard, with rows of figures arranged like the letters on a typewriter. When a deposit is made the teller places the depositor's book under a cylinder filled with movable figures on the side of the machine. Then he pulls the figures on the keyboard that represent the amount of the deposit. These figures are connected by wires with figures on the cylinder. The teller next moves a lever and that sets the machine in motion. The amount of the deposit is printed on the book and at the same time on a tape locked in a box placed just above the cylinder, so that a double entry is made. Should the teller make any mistake there in an ingenious contrivance attached to the machine that would prevent it from working and thus notify him of the error.

After the entries have been made in the depositor's book and on the bank's tape another cylinder is set in motion. This is in the middle of the machine and contains movable figures running up into the millions. These figures tell the total of the bank's receipts since it was organized and the amount that has just been deposited is added to it.

At the end of a day's business the officials of the bank add together the totals registered on the two receiving machines, deduct from them the total registered on the paying out machine, and strike a trial balance in a moment. The machines are inclosed in glass cases, so that every part can be readily seen.

Capacity in Gallons of Circular Tanks, Cisterns, Etc., for Each Foot in Depth.

Diameter in Feet.	Gallons.	Diameter in Feet.	Gallons.	Diameter in Feet.	Gallons.
1	5.87	12	846.03	23	3,108.0
2	23.50	13	992.91	24	3,384.1

Time Allowed for Assessment Work.

To the Editor:—If a quartz claim was located Feb. 3rd, '98, and $50 worth of work was done thereon inside of sixty days, work sworn in and recorded, no more work done on claim in '98, can this claim be jumped Jan. 1st, '99?

Chinese Camp, Tuolumne Co., Cal.

Not legally. In performing the $50 worth of work the State law has been complied with, and as the Federal law does not require the assessment to be done during the first current year after location, the claim was not open to relocation. The original locator has until Dec. 31st, '99, in which to complete his $100 worth of work.

Effect of the Smelter Trust.

Now that the big smelter combine is an assured fact, the next question of vital interest is: What will probably be the effect on the mine operator and the laborer in the enterprises which control the production of the ore and its transmission through the various stages up to the smelter?

It was predicted when the trust was in process of formation that its consummation would have a detrimental effect on the silver miner in various ways, and it was for the purpose of getting an expert guess on future developments that a reporter asked a prominent mine operator the general question: "What will be the probable effect on the producer?"

"It is almost too soon to make a close prediction," replied the operator. "But the combine is likely to close certain of the smelters after a time when they find they can produce bullion more cheaply without them. As to the bearing on ore producers, well—the trust dares not do too much. I anticipate its affairs will be regulated much as is the Standard Oil Co., keeping along in a pretty even way.

"There is one institution which will probably sooner or later become a reminiscence, and that is the public sampler. The ore will eventually go direct from the miner to the smelter. Now when a miner ships ore through a sampler, he is charged with the penalties, as on silica, for instance. The sampler mixes the ore to avoid the penalty and then sells to the smelter. The trust will undoubtedly take advantage of this, buy direct and do the mixing themselves. This phase of the situation will not, however, affect Aspen, as it is well known that the samplers here are run in connection with the big mining companies."

E. M. Taylor of the Taylor & Brunton Sampling Works Co. did not think there would be any appreciable change noticed by the producer for a period of at least eighteen months, on account of the formation of the trust. "After that time," said Mr. Taylor, "it depends somewhat on circumstances."

"I have reason to believe that there is no intention on the part of the combine to work against the producer and I do not think that any changes in the different smelting works are contemplated, at least not at present. Meanwhile, the holding for sale by one party of all the silver and lead produced in the country may have the effect of raising the price of those metals. The present management of the trust will certainly be favorable to the West and to the producer. Whether this condition will continue depends altogether, perphaps, on who will be elected in the future, and whether the future managements' affiliations will be with the Wall Street end of the combine more than with the West."—Aspen, Colo., Tribune.

A steel roadway, about 150 feet long, is being laid at the Minnesota Agricultural Experiment Station. The steel rails are 8 inches wide, with half inch flanges at the outer edge, and are 30 feet long. They are made of quarter-inch steel, with cross ties every 6 feet buried about a foot. On the ties are timber springs on which the rails lie. The width of the 8-inch rails takes in wagons of any width of tires. This demonstration of the steel roadway is being made in order to try to show its advantages over the ordinary macadamized road. It is asserted that such a road costs $2500 a mile, while a macadamized road costs from $3000 to $6000, and that the steel road will outlast the macadamized and be far more serviceable.

The chief of the Electrical Bureau of Philadelphia, Pa., David Walker, in his annual report states that at the close of the year '98 there were 7014 electric lamps in that city maintained at public expense—an increase of twenty-eight over '97. According to the returns made by the telegraph, electric light, telephone and street railway companies, there were in overhead service on the highways of the city, exclusive of those along railroad tracks, 54,795 poles and 10,100 miles of wires.

A new process is noted to preserve wooden telegraph and telephone poles. It is to surround that portion of the pole just below the surface of the ground with a terra cotta casing 24 inches long and of such a diameter as to leave a space of from 1 to 1½ inches between the pole and the casing. This space is then filled with pitch and clean gravel, forming a solid water and air tight casing around the pole to a depth of 24 inches.

The Commissioners of the Paris Exposition have been making some very satisfactory experiments with moving sidewalks for the transportation of sight-seers at the Exposition. These are similar to those at the Chicago and Berlin Expositions, but the Paris motive force will be supplied by electricity.

Latest Mining and Metallurgical Patents.

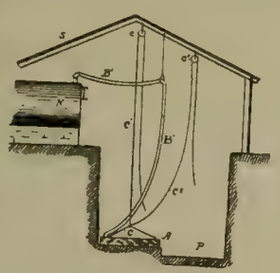
Patents Issued February 28, 1899.

Specially Prepared for the MINING AND SCIENTIFIC PRESS.

METHOD OF EXTRACTING GOLD FROM CYANIDE.—No. 620,100; W. A. Caldecott, Johannesburg, South African Republic.

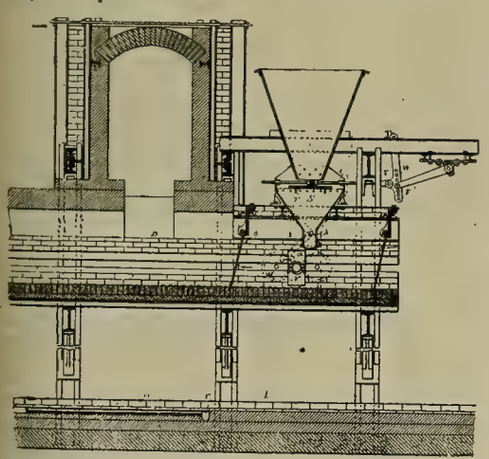
The claim is made of an improved method for the precipitation of gold from solutions containing gold-bearing cyanide solutions by the passing of such solutions over zinc shavings previously treated with a soluble salt of mercury, as perchloride of mercury.

STEAM THAWING APPARATUS.—No. 620,112; G. R. Elliott, Boston, Mass.



A thawing apparatus for sinking vertical shafts in frozen ground, combination of strong, flat, shallow box open at its under side, adapted to support men, tools and other heavy weight, coils of piping secured therein, an exterior supply of heated fluid and a flexible supply joining coils with supply, the box or hood being not half the area of the shaft floor, and transferring means whereby it being shifted back and forth upon the shaft floor, the latter can be continuously excavated and the work of the men not be materially interferred with. A combination of hood, steam coils suspended therein, source of steam supply, flexible connection uniting said steam source to coil, a structure supporting two pulleys at a distance apart equal to the width of hood, and ropes extending from hood over each pulley.

COMBINED ORE ROASTING OVEN AND COOLING HEARTH.—No. 620,132; H. C. Holthoff, Milwaukee, Wis., assignor of one-half to the Edward P. Allis Co., same place.

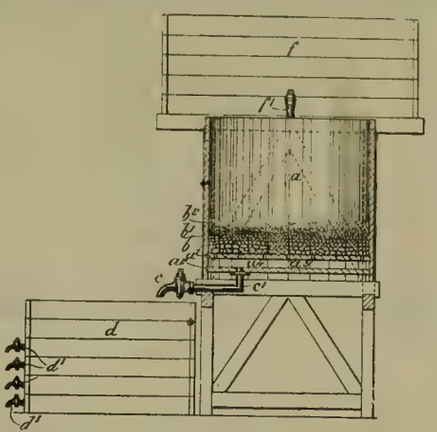


Apparatus for treating ore; combination of a hearth, chute located above, a gate or valve pivoted to chute, and designed normally to stand open; a rabble designed to pass over hearth beneath the chute; means for closing gate carried by the rabble; means carried by rabble for engaging downwardly-extending arm of bell-crank lever for closing valve as rabble passes beneath chute.

PROSPECTOR'S KNOCKDOWN CAMP STOVE.—No. 620,258; F. Stapp, Denver, Colo.

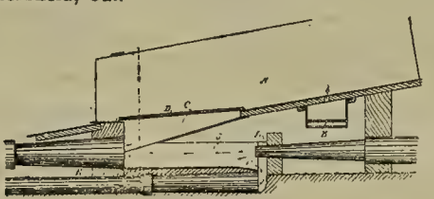
Combination of top plate; cooking apertures thereon having border edges trussed by two depressed curved steps; channel grooves all around edges of top plate and transverse truss between cooking apertures; sides and ends adapted to mesh in channels, base plate pivoted to ends, channel grooves therein adapted to receive and removably confine side pieces, with an oven supported between sides and compressing four independent side pieces arranged to interlock and intermesh at their edges; right-angled flanges at the ends of oven sides and clips secured to one side having a space between them and side adapted to receive flanges and projections on opposite side adapted to support adjacent ends of oven sides, oven, fire-box and oven doors.

PROCESS OF EXTRACTING GOLD FROM GOLD-BEARING SUBSTANCES.—No. 620,215; J. G. Black, Dunedin, and R. C. Skeet, Oamaru, N. Z.



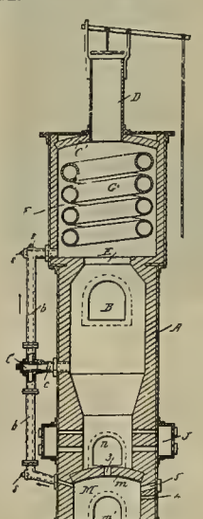
A process of extracting gold from ores, minerals or other gold-bearing substances, consisting in submitting such substances in a powdered condition to the action of solution containing sulphuric acid, chloride of sodium, and a manganate of an alkali metal and water, in the proportions of 100 gallons of water, from ten to twenty pounds of sulphuric acid, twelve to twenty pounds of chloride of sodium, and eight to nine ounces of a manganate of an alkali metal.

MINING APPARATUS.—No. 620,264; S. W. Wible, Bakersfield, Cal.



A combination with sluice having grating at discharge end adapted to separate larger from smaller material, the sluice having inclined bottom below grating and made convergent at discharge end; a conveying pipe, the inlet of which is substantially in line with and receives the discharge of the bottom; a concave segmental receiver in line with pipe and having its forward portion intersecting discharge of the inclined bottom at a point proximate to the inlet end of conveying pipe; and a jet nozzle in line with receiver and substantially in line with the flow of material down the sluice, whereby the jet discharged thereby joins the material moving down the inclined bottom of the sluice and directs the same into pipe.

CUPOLA FURNACE.—No. 620,339; H. E. Machell, London, England.

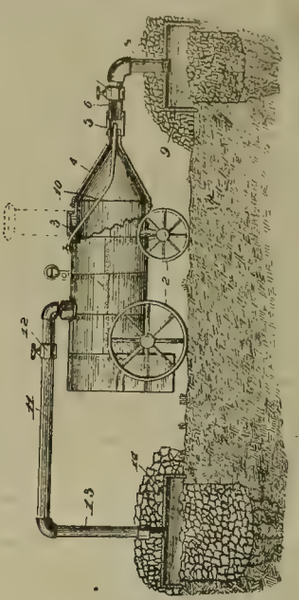


In a blast furnace, the combination, with a melting chamber open at the top and having a bottom *m* provided with a hole, a receiver M for the molten metal arranged below this bottom, and a heating chamber F above the top of the melting chamber and communicating directly with its upper part; of a blast pipe which passes through the heating chamber and is connected with the lower part of the melting chamber; a pipe *b* connecting the upper part of the receiver M with the lower part of the chamber F, and a branch pipe *c* connecting the pipe *b* with the middle part of the melting chamber above the point where the blast enters it.

AMALGAMATOR.—No. 620,328; A. H. Jocelyn, New York.

An amalgamating apparatus consisting of devices for supplying pulp and water, a sluice box and a loose-jointed amalgamating bed arranged in sluice box, consisting of removable amalgamating plates which interlock one with another so as to form a continuous amalgamating surface and prevent leakage at the joints, each amalgamating plate consisting of a stiff supplementary backing or body and a removable metal foil attached thereto.

PROCESS OF THAWING FROZEN GROUND.—No. 620,402; P. Anderson, Xenia, Ill.



First forming a shallow hole in the ground, then placing a charge of explosive material upon the ground and exploding it; then placing an open-bottomed box over the depression caused by the explosion and forcing heat into it from a suitably located generator.

The Naval Repair Ship.

Every officer in the American fleet at Santiago, from the admiral down, has praised the usefulness of the Vulcan. Her equipment was equal to that of any but large repair plants on shore, and the work actually done by her covered almost every conceivable part of the machinery of a war vessel, including repairs to hulls, gun mounts, dynamos, main steam pipes, main piston rods (for small ships), brass castings without number, and a considerable quantity of iron castings. This last is an especially interesting feature, as it is believed that the Vulcan is the first vessel ever fitted with a cupola for making iron castings. The object of such a ship is readily seen; it enables the vessels to have every repair, short of a breakdown of some of the larger parts, made on the station, when otherwise they would have been compelled to go at least several hundred miles, and in some cases more than a thousand, to reach a repair yard.—G. W. Melville, in the Engineering Magazine for March.

IN a paper recently read before the American Society of Civil Engineers, Julian Kahn, Jr., describes an ingenious arrangement, called an automatic railway, in use by the Calumet & Hecla Copper Co. The object of the apparatus is to convey coal from the hopper of the hoist to the store. Connecting the hoisting machine and this store is a line of rails inclined at a small angle towards the store. The car, having been filled from the hopper, runs down this incline by gravity, and near the bottom of the descent strikes an oak frame lying across the track. Connected with this frame is a weighted triangle which is swung upwards as the frame is pushed forwards. The resistances thus called forth bring the car to rest when it is automatically dumped. The weight then swinging back starts the lightened car up the incline again, with sufficient velocity to reach the top, when it is ready to take a fresh load and repeat its journey.

FROM Washington, D. C., comes the surprising statement that the U. S. naval authorities have decided that electricity shall not be made use of for operating the auxiliaries on the five new battleships now in various stages of construction.

The Genesis of Petroleum and Asphaltum in California.

NUMBER VI.

Written for the MINING AND SCIENTIFIC PRESS by A. S. COOPER.

Phenomena Attending Red Shales.—They are discovered by their bright colors, by the heat of the earth in their vicinity, sometimes by smoke. Sulphurous and other vapors frequently occur. These vapors in their course upward are condensed and incrust the fissures of rocks and even the surface of the ground.

Mineral springs, hot and cold, issue from the ground in their vicinity. The earth is charged with salts and minerals occasioned by the percolation and evaporation of these mineral waters. Shales, through the joints of which these mineral waters have flowed, have become impregnated with salts and the salts subsequently to the flow have become vitrified by heat. They are further known by the issuance of warm or cold natural hydrocarbon gas, by seepages of bitumen in their neighborhood, by fissures, joints and porous rock filled with asphalt and by the almost total absence of fossils in the burnt shale porcelanite and clinkers, which have been obliterated by hot water and heat. Before chemical heat commenced these shales did not contain over 2% of carbonaceous matter, not sufficient for them to be set on fire at the surface.

Physical Characteristics. — When unburnt these shales are easily split along their lines of lamination, but when burnt to a tile red or to a greater degree their fissility is partly destroyed. When unburnt their lines of lamination are plainly visible, but when burnt their lines of lamination are obscured or obliterated. When unburnt they have a clayey-like smell when breathed upon, but this physical characteristic is partly if not altogether lost when they are burnt. When unburnt and suspended so as to freely vibrate they have a dull sound when struck, but when burnt they become resonant. In this characteristic they resemble brick. Chemical fires destroy or partly destroy their lines of lamination, their fissility and their argillaceous smell when breathed upon, but increase their resonance. These characteristics do not occur when these shales are discolored by the oxidation of the iron naturally contained in them through the agency of water without heat. Serpentine cups filled with a pigment made from these bright shales are dug from the graves of the aborigines.

About thirteen miles east of Santa Barbara city an excavation was made on the bluff of the ocean for the roadbed of the Southern Pacific Railroad, and the gray shale charged with chemical substances and carbonaceous matter taken from the excavation was thrown over the bluff, forming a conical shaped pile, composed of pieces of shale containing from 1 to 8 cubic inches. Water could easily penetrate the broken shale and air could easily circulate through the mass. When the winter rains fell upon this pile chemical action commenced, producing sufficient heat to vitrify and weld the pieces of shale together. A large part of this shale was burned to a red porcelanite and the remainder was colored a buff shade graduating into the deeper shades of red. Above the railroad track the face of the shale bluff has been cut off to the angle of repose by the railroad company. This smooth surface is a good place to observe the action of chemical heat and attending phenomena.

La Patera Mine.—La Patera mine lies nine miles west of the city of Santa Barbara. Its relation with a lake and the ocean is shown in Fig. 4. The lake contains about sixty acres. Along the periphery of the lake the stratification of the shale dips towards the lake at an angle varying from 30° to 40°. The composition and the arrangement of the component parts of the soil are the same upon the island as upon the mainland. The shale must have existed at a level shown by the dotted lines in Fig.

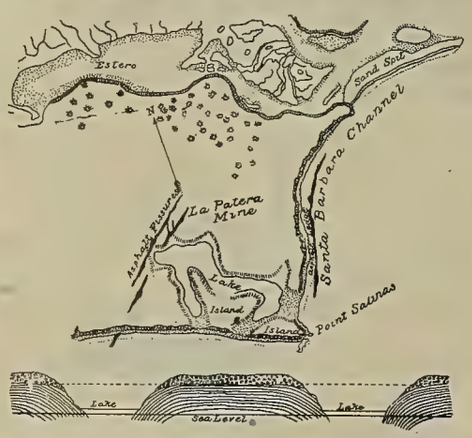


FIG. 4.—LA PATERA MINE, SANTA BARBARA, CAL.

4, and subsided after the deposition of the soil, otherwise the soil would not have been deposited upon the island in a manner similar to that of the mainland. This subsidence was probably occasioned by the contraction of the underlying shale, produced by chemical heat. Some idea of the contraction of the shale by burning may be learned from the contraction of brick through burning. Before burning and when in a dry condition a brick is 8 inches long; when burned—not vitrified—it is 7⅞ inches long, and when vitrified it is 7¾ inches long.

If the basin of the lake near the La Patera mine had been formed by erosion of the land by sea or surface water, the shale would have been squarely cut off and not contorted so as to dip towards the lake. In the excavation at the mine at the depth of 100 feet a temperature of 105° Fahr. is generated in the shales by chemical heat. Circumjacent to the lake are fissures filled with hard asphalt, through which comminuted shale and mineral water are disseminated.

Off the shore petroleum rises from submarine springs, covering a large surface of the ocean with a thin film of iridescent oil, the odor of which can be detected at a long distance. Ledges of hard asphalt exist in the ocean, below high tide, which run nearly parallel with the shore. Surface wells show the existence of water highly charged with mineral substances, in which petroleum is discovered. So far no potable water has been found near this mine.

Six miles west of Santa Barbara, on the Calera rancho, and on the ocean shore, an area of twenty acres has subsided some 25 feet; of this subsidence, 4 feet occurred in five years. This subsidence has occurred through the contraction of the shale. The surface of the subsidence is rifted and seamed, and from these rifts and seams sulphurous and other vapors ascend. The ground is hot. The bluff is composed of burnt shales showing tints from a cream color to brilliant red. Water containing salt seeps from the base of the bluff. Shales with carbonaceous material, shales saturated with bitumen and smoky-looking shales surround the hot places. Near the hot places heavy petroleum oils ooze through the shales. To the eastward and westward heavy and thick petroleum tars ascend through the cracks and seams and joints of the shale. Some of the seams of shales, containing a small proportion of bitumen, have hardened to such an extent that they resemble dark flint and will cut glass.

Lyell gives the following: "Captain Mallett quotes Guinillar, as stating in his description of the Orinoco, that about seventy years ago a spot of land on the western coast of Trinidad, near half-way between the capital and an Indian village, sunk suddenly, and was immediately replaced by a small lake of pitch, to the great terror of the inhabitants. A similar subsidence at an earlier period may probably have given rise to the great pitch lake of Trinidad, the cavity having become gradually filled with asphalt." There are a number of places in California near these red shales from which natural gas issues. Some are hot, showing that they are formed at high temperature. It may not be out of place to mention in this connection the occurrences of red shale in other parts of the world in which bituminous deposits are known to exist.

Fig. 5 is a view of a small lake formed by the subsidence of the land near Mount Solomon, in Santa Barbara county.

(To be Continued.)

FIG. 5.—LAKE FORMED BY SUBSIDENCE OF LAND.

The Feedwater of Stamp Mills.

In a paper prepared by Bernard MacDonald, M. E., of Montreal, Canada, read before the Canadian Mining Institute, March 1st, '99, the author has introduced a new idea in supplying mortars in gold mills with feedwater. The author of the paper says:

"In considering this question it should be understood that a continuous and uniform stream of water is required in the mortars of the stamp mill to mix with and form a thin pulp of the ore as it becomes pulverized beneath the blows of the falling stamps and in this condition (thin pulp) to carry it in suspension until discharged through the screen meshes.

"It is customary to introduce the water required for this purpose over the top of the mortar in iron pipes or rubber hose. Thus introduced the water falls about 3 feet before it reaches the top level of the pulp mass in the mortar where it is still about 7 inches above the crushing surfaces of the shoes and dies. On reaching this position it will be seen that a large portion of it must of necessity be discharged from the mortar before it can be mixed with the ore as it is pulverized. Therefore such portion fails to effect the purpose for which it was introduced. But perhaps the greatest defect in this system is the fact that the feedwater falling on the pulp mass has a tendency to settle the fine sands and slimes below the discharge level which not only lessens the discharging capacity of the mortar, but subjects the fine sands to further pulverization after having reached the proper degree of fineness to pass through the screens, thus producing loss by sliming the pulp and unnecessary abrasion of the free gold particles.

"The points of superiority claimed for the 'improved' method are that the water, being introduced below or on a level with the crushing surfaces of the shoes and dies under a static head, sweeps off at once from the dies and between them such portion of the ore as has been reduced to a sufficient degree of fineness, and carries it upward into the pulp mass, where it is immediately presented with the most favorable opportunity of being 'splashed' through the battery screens. This removes, to a very considerable degree, the cause of sliming the pulp for which the stamp mill has been noted, and, as will readily be seen, increases the discharging capacity of the mortar and hence its crushing capacity. In thus washing away the fine sands and slimes from around the dies, leaving only the coarser particles of ore to occupy these spaces, a favorable receptacle is provided into which the coarse gold may settle and be protected from unnecessary abrasion. Were the water introduced in the customary way, the spaces around the dies would be packed with an impenetrable mass of silt which would offer no hiding place for the coarse gold which would be lashed hither and thither through the mortar, losing by abrasion with every contact between the stamps and dies or with the sharp quartz. Summed up, the points of advantage in this method are:

"(1) Increase of crushing capacity.

"(2) Decrease of sliming.

"(3) Preparation of the bottom of the mortar to retain and protect the coarse gold from abrasion.

"It was feared at first that the holes for admitting the feedwater to the mortar might become choked up with pulp inside the mortar, but one month's continued operations without any symptoms of trouble from this source has proved these fears groundless.

"The head under which the water flowed to the mortars in the case under consideration was 30 feet."

This idea is in the experimental stage, though the writer states that it has been in use for a month. While it is quite possible that feedwater introduced at the level of the top of the die may give increased capacity, it seems unsuited for mills where amalgamation is practiced inside the battery. An insight into what really takes place within a battery can only be gained from a close inspection of the material in the mortar when the stamps are at rest. It is usually the aim of mill men to save all of the gold inside the mortars that can be secured without too seriously affecting the capacity of the battery. The MINING AND SCIENTIFIC PRESS will be pleased to receive from mill men opinions on this subject and on kindred subjects relating to the treatment of ores in stamp mills.

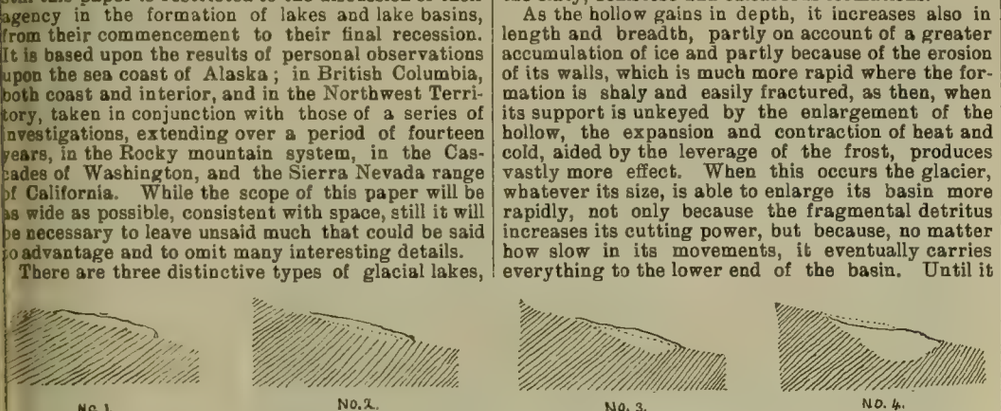
Glacial Agency in Lake Formation.

Written for the MINING AND SCIENTIFIC PRESS by A. THURSTON HEYDON, M. E.

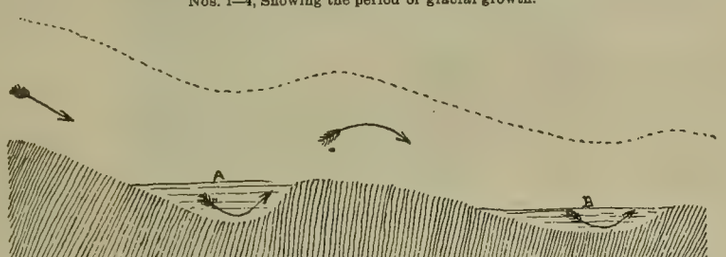
While many lands are either endowed with glaciers or else bear more or less well defined evidences of past glaciation, the far Northwest is the place of all places in which the various stages of glacial action can be studied to the best advantage. That region contains the whole history of glaciation in one volume, yet with a comprehensiveness and fullness of detail unobtainable elsewhere. There, glacial growth can be traced from the small patch of granular snow remaining upon a protected spot when the autumnal frosts return, to the immense iceberg-forming glaciers, such as the Muir, to its decadence, from the first evidences of recession to the vast areas planed off, the valleys carved and the lake systems scored out by the icecaps, whose degenerate remnants are still existing in the sheltered gorges of the higher mountains. Everything is there, without a missing page or an omitted paragraph.

While whole libraries could be written and illustrated without exhausting the subject of glaciers, still this paper is restricted to the discussion of their agency in the formation of lakes and lake basins, from their commencement to their final recession. It is based upon the results of personal observations upon the sea coast of Alaska; in British Columbia, both coast and interior, and in the Northwest Territory, taken in conjunction with those of a series of investigations, extending over a period of fourteen years, in the Rocky mountain system, in the Cascades of Washington, and the Sierra Nevada range of California. While the scope of this paper will be as wide as possible, consistent with space, still it will be necessary to leave unsaid much that could be said to advantage and to omit many interesting details.

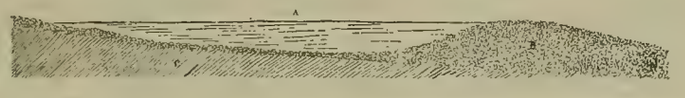
There are three distinctive types of glacial lakes, viz.: the first class, which are usually the first of a series or system or else either flank or are entirely independent of such series, and, being formed by local action, are typical of the rise of a glacial epoch; the second, which occupy basins hollowed out by the flowing glaciers and are typical of the maximum of the epoch; and the third class, which are restrained by morainic dams built by the retiring glaciers, and are characteristic of glacial decadence. Although these are the three distinctive types, the majority of the glacial lakes are a blending of two, and, occasionally, of all three types. For instance, what would have been a lake of the first class becomes one of the second when its basin was used by a glacier descending from above it, and the second partook of the characteristics of the third when its outlet was moraine dammed. The above types and variations are characteristic of glacial action, whether in one of the great icecaps or in a local glacier.



THE FORMATION OF GLACIAL LAKES OF THE FIRST CLASS.
Nos. 1—4, Showing the period of glacial growth.



A. B.—GLACIAL LAKES OF THE SECOND CLASS.
The dotted line represents the glacier which hollowed out the lake basins. The arrows represent the line of greatest force in the glacier.



A.—GLACIAL LAKE OF THE THIRD CLASS. *B.*—DAM FORMED OF GLACIAL DETRITUS. *C.*—BEDROCK.

The initial step in the formation of a lake of the first class is a patch of snow upon a flat or a relatively gentle slope, so situated that it remains unmelted until the snow flies again. As the formation beneath it is kept moist when that surrounding it is comparatively dry, or else thawed when the rest is frozen, it has more time for decomposition and so is more easily disintegrated. Unless the grade and formation or the vegetation at that point are just right, the waters from the melting snow will cut a channel, with the result that a ravine, instead of a lake basin, is formed; but if the overflow passes over a bit of harder formation, or clay or mossy ground, the disintegration of the formation beneath the snow is more rapid than the erosion immediately below it, and first a flat and then a hollow place is the result. While the fragmental rock, grit, etc., with which a glacier is shod, acts like a rasp upon the formations over which it passes, still the pressure and friction of the ice itself, with its various temperatures, play no inconsiderable part in glacial erosion, and both are greatly assisted by the water, which, in addition to its torrential force, aids in the chemical decomposition of the rocks. In the commencement of a glacial lake basin, the rasping action is relatively at a minimum, while that resulting from frost, ice and chemical decomposition is at a maximum.

The products of purely mechanical erosion at this stage are usually fine enough to flow off in suspension along with the insoluble products of chemical decomposition, while the others are carried off in solution. The milky, greenish and bluish-white, the green, bluish-green and blue tints of the various glacial streams simply result from the reflection of light by the infinitesimally fine particles of matter held in suspension. The effect of all this is to produce a hollow which all of the forces tend to enlarge at a rate commensurate with its increase in size. The more easily disintegrated or shaly the formation the greater the results in a given time. For this reason, although there are many glacial lakes in the granites, the larger and deeper ones are found in the slaty, schistose and calcareous formations.

As the hollow gains in depth, it increases also in length and breadth, partly on account of a greater accumulation of ice and partly because of the erosion of its walls, which is much more rapid where the formation is shaly and easily fractured, as then, when its support is unkeyed by the enlargement of the hollow, the expansion and contraction of heat and cold, aided by the leverage of the frost, produces vastly more effect. When this occurs the glacier, whatever its size, is able to enlarge its basin more rapidly, not only because the fragmental detritus increases its cutting power, but because, no matter how slow in its movements, it eventually carries everything to the lower end of the basin. Until it flows over the lip of the basin the glacier protects it by riprapping it with the morainic matter deposited upon it.

All of these forces tend steadily in one direction, viz., the enlargement of the basin, which increases in size from the dimensions of a puddle to those of a pond, and eventually to those of a lake, the size attained being regulated by the excess of the annual snowfall over the annual thaw, the changes of temperature and the life of the glacier. The life of the basin itself is limited by the ability of its lip to withstand the forces of erosion, and after it becomes a lake basin, in addition thereto, it is limited by the amount of sediment and drift deposited in it.

The second class of glacial lakes results, in favorable spots, from the action of a glacier, moving on its course, planing off eminences, obliterating some depressions and making or enlarging others. As the rock-shod glacier plows along, it cuts its way deeper and deeper. While at first it usually remodels a watercourse to suit its needs, still, after it has attained mass and momentum, it fills up old valleys with morainic detritus and carves new ones. Should a mountain range play the part of an obstructionist, it is cut through forthwith. The massing up of the ice before the passage of a range or other obstruction and its spreading out after the compression of the passage form basins on both sides, while smaller ones are scored out between.

The glacier glides on like water, only at an infinitely slower rate, up and down and around the obstructions in its course. A vertical section shows that its course consists of a series of convex descents and concave rises, which blend into each other with the most beautiful curves in a firm formation. The smaller ones are frequently very perfect, while the larger ones run on broader lines and are more subject to variation from changes in force and direction as well as differences in the hardness of the formations. But large or small the principle is the same. As in a glaciated surface, puddles lie before and after a pitch, so lakes are found in the same relative positions. Unless filled in by detritus, the deepest portion of the lakes, with the exception of the holes in easily disintegrated formations, as well as of the puddles, is near the lower end at the point where the downward force gained by the ice in its descent was spent and it arose on the rebound. The point down the lake at which this occurs depends upon the steepness of the pitch and the thickness of the glacier.

As long as a glacier is growing and moving forward, so long will it have no terminal moraine to speak of, but when it comes to a standstill and then begins to shrink, it builds a terminal moraine which varies in size with the speed of recession. As it will remain stationary longest where there is a narrow outlet for a large body of ice, the accumulation of drift will be the largest at such a point, and form a dam. While such dams are usually at the lower end of a basin where the waters supplanting the receding glacier would have formed a lake without their aid, still sometimes, from a temporary lull in the rate of recession, dams are made and form lakes of the third class where otherwise there would have been none.

It must not be supposed that lakes occupy all of the basins made by glaciers, as it depends upon their rates of recession as to how much of their courses are filled in with morainic matter, and the rolled gravels and silts resulting from the torrents to which their melting gives rise. The facts are that, on account of the lowering of the lake levels by the wearing away of the lips of their basins as well as the accumulations of silts, etc., a large percentage of the glacial lakes are extinct long before the glaciers which formed them have retired into the mountain fastnesses from whence they sprang. On account of the comparative ease with which lakes of the third class cut through the dams with their overflow, they are the shortest lived of all, while those of the first are the longest in proportion to their size, as having but little glacial detritus around them they are practically only filled in by the products of subsequent erosion.

Miners' Range, N. W. T.

The Science of Prospecting.

Written for the MINING AND SCIENTIFIC PRESS.

The question is frequently asked, "Why are not scientifically educated mining engineers the discoverers of more rich mines?" Briefly, the answer is: because they do not prospect. Undoubtedly men who have the advantage of a technical and scientific training in mineralogy, metallurgy, geology and engineering are better qualified to prospect intelligently than those who have not had these advantages, but usually such men are otherwise employed and have little time to prospect, even if so disposed.

A technical education without practical experience does not fit a man for even such an humble occupation as prospecting. While a prospector, whose chief reliance is in his muscle and not in his technical education, may accidentally stumble upon a valuable ore deposit, he is out looking for mines, and as all rocks look much the same to him it does not concern him whether he picks up quartz, limestone or a fragment of some eruptive rock, for either may contain precious metals, and his very ignorance of the character of the rock is his safeguard. All miners, whether technically educated or not, are prone to search for mineral deposits, veins, float, etc., similar to those they are familiar with. To the Comstock miner the ideal mine is found in the bonanzas of the Comstock; the Homestake miner looks for broad zones of quartz and schist colored red by oxidation; the Leadville miner is in search of a contact of lime and porphyry; the Californian wants black slate and greenstone; the Butte, Montana, miner thinks granite a fine formation for mineral; the Arizona prospector will camp with a rotten, iron-stained porphyry dyke; the development of the Cripple Creek mines has created a demand for phonolite, and in the Black Hills of South Dakota the discovery of gold near Ragged Top has made "arrowhead flint" the proper material in which to seek gold; the miner from Calico, California, is always on the lookout for large masses of peagreen breccia, in hope of finding chloride again; the digger from South Africa is satisfied with a conglomerate reef and recognizes one at sight; the miners familiar with Silver Reef, Utah, know that some white sandstones and drab clay shales contain high-grade silver ores. And so in endless variety of form and occurrence the miner from each region looks for the characteristics with which he is familiar. While the prospector may locate anything to which his notion inclines him, he locates much that is worthless and doubtless passes much that is valuable, where the technically educated mining engineer would probably recognize the worthlessness or the value of any particular occurrence were his attention directed to it; but, as previously stated, he is not prospecting. It is rarely that the technically educated, experienced mining engineer

makes a mistake by condemning a valuable mine, though he may admit possibilities for some undeveloped mines which never materialize. In all undeveloped mines there is an uncertainty and the element of chance cannot be disguised. Often a too great willingness to take this risk results disastrously. When the Commonwealth mine, in Cochise Co., Arizona, was in the prospective stage it was visited by a technically educated mining engineer, who, after an examination, purchased the property for a large sum. Those familiar with the history of the mine know no mistake was made. The existence of telluride ores rich in gold at Cripple Creek was made known through the discovery of float by a technically educated mining engineer, who recognized the telluride.

Since, then, gold is found in paying quantities in such a variety of rocks, of so many different geological ages, and is associated with such a variety of minerals, it may be considered unwise to pass any rock by without attention as unworthy of notice. Within the personal knowledge of the writer gold and silver occur in the United States in almost every kind of rock known to science, with the exception of feldspar-basalt and rocks of that extremely basic type and obsidians or vitropheres and rocks of the extremely acid type. Undoubtedly quartz is the mineral most commonly associated with gold, but gold also occurs with calcium carbonate, feldspar, garnet, in aggregates of mica scales, in hornblende, in coal, and in slates, in granite, sandstone, limestone, diorite, andesite, rhyolite, and, in fact, in every variety of rock. Some dykes are gold-bearing without showing any considerable alteration or silicification. It would seem, then, that the prospector should test every rock formation, whether familiar or not. The men who made the first quartz discoveries at Randsburg, California, were dry washing for placer gold, and, it is said, knew so little of mines and mineral veins that as they approached the croppings of one of the most famous veins in that camp, in the course of their placer work, used to sit upon the outcrop and eat their lunch, little dreaming that the blackened honeycombed rocks were rich in the very metal they were striving under such difficulties to obtain. Of the great army of prospectors who are found throughout the mining region there are, perhaps, comparatively few who would not recognize a vein when they saw one, but such cases are of record. W. H. S.

The Alluvial Deposits of Western Australia.*

NUMBER II.

By T. A. RICKARD, State Geologist, Denver, Colorado.

In mountainous regions the disintegration of the surface is mainly caused by the frost. Water penetrates into crevices and cracks, and, because its maximum density is at 4° C. and not at zero, it undergoes such expansion in the immediate approach to the freezing point as to become a powerful lever for tearing the rocks apart. Thus is loosened that material out of which eventually the alluvial deposits of the valley are formed. In warmer climates the contraction and expansion of water is likewise a ceaselessly destructive agent. Even in a dry, hot region, such as the interior of West Australia, the difference between the heat of day and cold of night causes the dew to play an important part in moulding the physiography of the country.

A low ridge of the desert is crested with the outcrop of a gold-bearing quartz vein, which, amid that surrounding sea of dark blue scrub, justifies its colonial designation, a "reef." On its flanks there is a thin cover of sandy soil which gradually thickens, a little lower down the slope, to a deposit of several feet. Sink a hole and you will find, first an inch or two of loose sand and dust, then a more solid layer of gravel and dirt, which in turn passes imperceptibly into a compact material consisting of fragments of rock and quartz, held firmly together by clay. It is called "cement," and it might better be termed an "agglomerate." It is an unclassified product of erosion and lies close to the place of its origin, as a mere collection of unsorted debris.

The rock on which the deposit rests is so softened by decomposition that it is frequently taken for a part of the overlying detritus. if the hole be continued so as to become a well or shaft, it will penetrate through additional oxidized ground until this suddenly gives place to diorite or granite (the two prevailing formations) at a depth varying from 75 to 200 feet, which is the drainage level of the region.

This deposit owes its existence to the wind and rain, assisted by gravity acting on a slightly inclined surface. Wind is ordinarily an insignificant geological agent, but in the constant and violent draughts of a high plateau there is a force which, working during long periods of time, is capable of producing notable results. In the vicinity of Coolgardie and Kalgoorlie, especially the latter, which has the less broken topography, the dust storms are almost ceaseless, and bear forceful testimony to the amount of material which can be conveyed in the air.

The whirlstorms spring up suddenly, rush madly across the plain, suck up everything lying loose on the surface, and as suddenly subside. These apparently erratic air disturbances are responsible for the transport of the greater part of the material which weathering and erosion have disintegrated.

In traveling over the country one is soon called upon to notice the broken white quartz scattered over the ground in big patches many acres wide.

The granite is kaolinized to an almost incoherent clay, and the diorite is rendered abnormally heavy in iron by the surface concentration of decomposition products. And as the rock is eroded the quartz, on account of its hardness, persists, so that a series of small stringers eventually yields an accumulation suggestive of its derivation from a large mass. It is a process of concentration which, there is reason to believe, has also affected the gold occurrence, the upper portions of veins being enriched by the deposition of the gold left behind from lode matter which was long ago disintegrated and removed by erosion.

If we now turn to the "dry blower" and watch

FIG. 2.—DRY BLOWER AT WORK.

him at his work we shall see the same processes utilized in the winnowing of the gold.

Dry Blowing.—In West Australia the absence of running water renders unavailable the cradle and the sluice box of ordinary placer mining, with the result that the prospector has learnt, intuitively, to utilize the agency which he sees incessantly at work in the nature around him. Wind replaces water. The method is simple. Taking two pans, which the Australian calls "dishes," he places one of them on the ground, empty, while into the other he puts a shovelful of the "dirt"—that is, the sandy detritus containing the gold. The material is shaken up so as to bring the big lumps on top, and then, resting the pan on one knee and holding it with his left hand, he uses the right hand to skim off the coarse particles. Then, standing erect and facing at right angles to the direction of the wind, he slowly empties the full pan into the empty one at his feet. As the stream of dry dirt falls, the wind selects the fine and blows it in a cloud of dust to leeward. The operation is then reversed, the pan which has just been emptied being placed on the ground so as to receive the contents of the other. This is repeated three or four times, according to the degree of concentration effected. In a strong breeze one operation may prove sufficient. To prevent the loss of the fine gold which is sometimes carried away with the dust, it is customary to spread a piece of canvas on the ground, one end being placed under the pan and the other extending to leeward. The next stage is to further winnow the material by tossing it up and down in the pan (see Fig. 2). The latter is held slanting forward, and is jerked so as to throw the dirt from the front to the back of the pan. The light particles ar separated, as chaff is driven from grain. Then, gi ing the dish a vanning movement, the prospect again removes the coarser particles that come t the surface by skimming them off with his han There now remains about half a pint of material, an this is diminished by panning, just as in water, th dry particles having a mobility permitting th method of treatment. Finally he drops on his kne and, holding the pan so that it is tilted forward, b raises it up to his mouth and uses the breath of h lungs to complete the process. The particles of gol are seen fringing the edge of the iron sand. If th yield consist of only a few minute particles he put his moist thumb on them, and so transfers them t his pocket; but if there be any coarse pieces—nug gets—they are put into the leather wallet attache to his belt.

In watching a dry blower at work it becomes ev dent that the operatio like every process of co centration when properl conducted, consists of si ing and classification. Th wind removes the fine san and the dust, the opera tor's hand skims off th larger lumps of dirt, s that there finally remain a collection of those heav particles of ironston which, as in ordinar placer mining, accompan the gold.

Owing to the perfec dryness of the dirt an the heat imparted to th surface of the iron pa under a tropical sun, th material behaves wit much of the mobilit which it would have i water and not air wer the vehicle employed. I reminds one of the be havior of a charge in th roasting furnace, in whic the hot air cushions eac particle so as to give t the mass an apparen fluidity.

The rapidity and com pleteness of the operatio depend on the strengt and uniformity of the wind. There is a constant light breeze on the gold fields, even during those happy intervals when the dust-whirls have tempora rily subsided; but the cloudy mornings of the wet season and the sultry days of the hottest sum mer months are alike unfavorable to dry blowing, because at such times the air is dead. Many of the mining camps are situated on a slight rise of ground, overlooking those desolate sinks of salt and sand which are called "lakes;" and the difference of level is marked by a constant breeze which is a good friend to the dry blower.

In the history of ordinary alluvial mining, washing with the pan was succeeded by the use of the sluice box and the cradle. Similarly the "dishes" of the dry blower are replaced by machines of several types, all of which, however, are based on the idea of a shaking movement in the presence of a current of air. The simplest contrivance is represented in Fig.

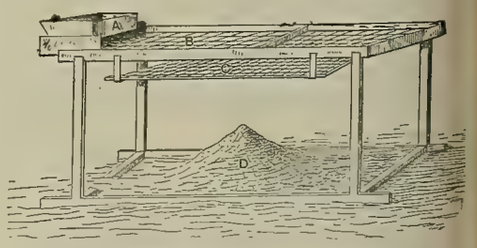


FIG. 3.—DRY BLOWING MACHINE.

3. This machine is 2 feet wide and 4 feet long. *A* is a hopper with a sheet iron bottom punched with 1-inch holes, *B* is a 12-mesh screen, *C* is an 18-mesh screen, and *D* is the final product of the operation. The dry blower empties a shovelful of dirt into the hopper, places his hands on the two sides of the machine and shakes it from side to side. There is sufficient play in the frame itself to permit a movement which causes the material to pass through the series of screens and accumulate underneath.

(*To be Continued.*)

* Condensed from paper read before the Am. Inst. M. E.

Mining Summary.

ARIZONA.

Near Prescott on the 3rd a fire in the Big Bug mine resulted in the complete destruction of the stamp mill and the hoist of the Red Rock Milling Co. The mill had just been completed at a cost of over $20,000 and had not been run. Loss $25,000, no insurance. The property belonged to Spruance, Stanley & Co. of San Francisco.

At the Black Diamond group of mines, in the Dragoon mountains, the contractors who are doing 200 feet of work report striking a rich body of sulphide copper ore; 20 feet of the ore is opened up.

A strike is reported in the Oriole mine, at old San Domingo, eight miles east of Wickenburg. The Oriole was located a year ago by the Ardath G. M. Co. of Indianapolis. The Ardath Co. have sunk a shaft to a depth of 100 feet and have done a good deal of drifting. They have now about 800 tons of ore on the dump. The new strike was made on the west drift, disclosing a vein 2 feet wide, which assays $300 a ton. Machinery for a stamp mill is on the way to the mine.

On the Silver Trail mine, one of the Sundance group on the Hassayampa, near the Senator mine, a rich strike is reported at a depth of 220 feet. The ore body is 4 feet wide.

J. H. Costello has started the mill on the Trilby mine, in White Picacho district. The mine is well opened.

The Black Warrior Copper Co. at Globe has let a contract to drive a crosscut tunnel 225 feet on the Dadeville.

The railroad to the Old Dominion mine is completed and the smelter operating. It is expected it will turn out 30,000 pounds per day. When the smelters have not been working the force has been reduced to 100 men. It is expected that 300 men will soon be employed by the company. The Old Dominion is still looking for sulphides to mix with its richer ores. Nearly all the other big copper mines in Arizona are now producing their copper from sulphides.

The Boston News Bureau asserts that Lewisohn Bros. & Co. backed the Arizona Copper Co. to the extent of some millions of dollars, and have finally brought it to such a state as to make its 160,000 shares, which are sold in the London market and mostly owned by Scotchmen, worth about $55 per share, or $8,000,000 for the property, whereas a few years ago it was heavily in debt and could be bought for less than $2 per share.

Journal-Miner: M. S. Taft has shipped five carloads of ore from the Sterling mine, on Big Bug, which netted him $800 per carload.——Preparations are being made to sink the Senator shaft to a greater depth.——On the Polar group of mines, in Black Rock district, a 75-foot shaft recently sunk develops a vein 30 inches across.

CALIFORNIA.

Amador.

The shaft at the Bay State mine, four miles north of Plymouth, is being sunk to 1000 feet by contract.

The shaft at the Amador Queen No. 2 is down 800 feet. Some valuable ore has been taken out.

It is reported that H. W. Brown of Salt Lake City, Utah, has paid $100,000 for a quarter interest in the Ivanhoe mine, two and one-half miles northeast of Plymouth. The Ivanhoe is about 40 feet between walls and consists of amphibolite schist through which occurs a reticulated mass of small quartz stringers. The ground is soft and is quarried at present at small expense.

Butte.

The new 40-stamp mill at the Banner mine near Oroville is running steadily and miners are being put on every day. The new mill is provided with cement mortar blocks and electrical power.

Calaveras.

The 10-stamp mill at the Ford mine near San Andreas was completed on the 1st inst. Electric power will furnish light and run the mill, concentrators and rock crusher, and the batteries will be supplied with water from the mine, for which purpose two 10,000-gallon tanks have been erected.

At the Gwin mine a new shaft is being sunk. The grading for the new mill is still in progress. Most of the grading was done by the hydraulic method under a pressure of 300 feet.

It is reported that pay gravel has been struck on French Hill one mile from the town of Mokelumne Hill, in a shaft at a depth of 75 feet.

The Lightner M. Co. at Angels have their electric machinery in place and the 20-stamp mill is run by electricity. The foundation for a new compressor is completed and the compressor is being set up. Three air receivers will be put in connecting with the compressor.

The machinery has been removed from the Great Western mine, near Altaville, by the Drake M. Co., Ltd., and has been taken to Ghost mine, near Angels. It is said that the Drake Co. has secured the extension between the Ghost claim and the cross shaft. The price is reported to be $90,000.

Work at the Green Mountain hydraulic mine on Chili gulch is progressing. At this mine is a derrick having a 75-foot "boom." Three hundred inches of water are used. J. Burton is operating the mine.

The Drake Properties, Limited, in the southeastern limits of Angels, has an option on the Last Chance mines, adjoining their property. The company has also bought a water right on Stanislaus river at Bostwick's Bar.

Work on the Admiral Von Tromp mine near Pine Log is to be resumed.

There are over 100 miles of ancient river channel in Calaveras Co., of which not less than twenty-five miles remain intact.

Boston capital is now invested in Melones G. M. Co. There are 200,000 shares, par value $10. The property was bought for $182,500 cash and 13,250 shares of the stock. The directors are W. E. C. Eustis, C. M. Weld, I. T. Burr, J. Parker, J. C. Whitney, C. N. Felton, W. C. Ralston. The 100-stamp mill will be completed in November, when it is expected to employ 175 men and mill the ore for less than $2 per ton. The stock sold in Boston last week for $6.50 per share.

There are rumors of the Fox or Tozier mine at Angels being reopened. This property joins the Utica on the north.

Del Norte.

Miners near Crescent City are making examination of their beach claims with a view to sinking deeper than has ever before been done by those who have carried on mining there.

El Dorado.

The Union mine at El Dorado has added an electric plant for lighting.

Work will soon begin by the Harpending Co. on the Central mine near Church Union.

The Starlight mill has started up.

The Morrison mine near El Dorado will be reopened.

Prospect: The Ritter mine on Murray creek ridge, two miles north of El Dorado, is an old location, covered by a U. S. patent, and was worked in the fifties but abandoned. It was reopened by E. C. Rigney last November and has been prospected to a large extent. The tunnel has reached a depth of 285 feet, 260 feet of that distance being on the pay shoot. The shaft, sunk from the apex of the ledge, is down 75 feet, and in 75 feet more will tap the tunnel.

Kern.

The St. Elmo near Randsburg is being worked again after an idleness of many months under a lease to the Johannesburg Reduction Works with W. Walker as Mgr. The lease requires that they sink a number of feet each month in addition to drifting and stoping.

Golden Bros. are shipping a carload of ore from the Slate range via Johannesburg to Selby & Co., San Francisco.

The California Borax Works northeast of Randsburg have commenced work and are shipping their first lot of borax.

The Little Butte Co. at Randsburg has built a stamp mill at Dove Springs which is now in operation.

A 20-ton capacity cyanide plant has been completed at the Red Dog mill. The mill is running on ore from the Kinyon and Ruby mines.

Miner: It is expected that the cyanide plant at Cuddeback Lake will begin operations the first of the week. They have a complete plant and will be able to handle twenty tons a day.

Mono.

The stockholders of the Standard Consolidated M. Co. have authorized a reduction of the capital from $20,000,000, divided into 200,000 shares of the par value of $100 each, to $2,000,000, divided into 200,000 shares of $10 each. Since the new mill started up the gross output has been $38,475.19.

Napa.

The Vallejo Quicksilver M. Co. has levied an assessment of 2 cents per share, delinquent March 20.

Nevada.

The Pennsylvania M. Co. of Grass Valley has paid a 5-cent dividend, making the 27th. A new mill building is about completed at this mine and the machinery is being put in place.

At the Eagle Bird mine in Maybert recently a rich strike was made on the sixth level, the ledge being 5 to 8 feet wide and the quartz showing free gold.

The *Union* says negotiations are pending for the sale of the Eagle Bird mine at Maybert to an English Co. C. R. Rowe, representing E. A. Burr & Co. of London, England, who transacts the business for the company is in Grass Valley.

Placer.

Herald: At the Marguerite, near Auburn, work is going on.——The tailings at the old Chicago mine are being treated by the cyanide process.——Rymal & Jones struck a pocket from which they took out over $1600. A few days ago after prospecting three days. The gold runs over $19 an ounce. The claim is near Pilot Hill.——The Hathaway, near Ophir, will soon extend its pipe line to the top of Boulder ridge.

Plumas.

The Genesee mill is again in operation. Mrs. Gruss has recently build a furnace provided with a boiler for supplying the batteries and plates with water at the desired temperature to improve amalgamation.

Riverside.

The Mammoth mine near Menifee has a large vein lying at a low angle in granite. It prospects quite regularly. The vein has been opened by several surface cuts and tunnels extending into the hill from which crosscuts have been run. Over an acre of quartz is blocked out, having a thickness of about 7 feet.

The mines at Virginia Dale owned by Ingersoll & Esler of San Bernardino are turning out over $100 per day.

Siskiyou.

The recent storm has resulted in starting work in several claims on the flats and in the gulches around Yreka.

The company which bonded Yreka creek also bonded Cottonwood creek, and will begin prospecting the ground on that creek with steam-boring apparatus.

A. Erno is putting up a new hoisting plant at his claim in Quartz valley.

A Denver, Colo., company has bonded a mile of Cottonwood creek, near Hornbrook, and also the ditches and property of W. H. Smith, near Henley, in the same section, with a view of putting in a dredger.

Negotiations are in progress for the Louis Nehrbass ranch at Greenhorn creek, adjoining the Blue Gravel mine, for mining purposes. A company represented by F. D. Frazer and W. H. Crooker, who are making this deal, will also bargain for Rostel's place.

E. Wallace has bonded land along Yreka creek for the purpose of mining by dredger process.

Some rich ore has been found in the Growler mine of Corbett & Parker, in the Wagner Creek district, recently.

Yreka *Journal*: Miners at Greenhorn Blue Gravel mine are getting back to the pay where the cave occurred lately. There is an abundance of water in the creek for washing and a better supply for pumping from the bedrock.——Mining at Cherry creek is in progress, since the late storm furnishes a supply of water for placer mining.——Spengler Bros. will start work at the mouth of Humbug, and with more rain or snow can continue steadily.——R. L. & S. M. Atkinson have located numerous quartz claims in Snowden district, on Shasta river. The quartz ledges in that section are similar to those in the Fool's Paradise district adjoining, and along Shasta and Klamath rivers.

San Diego.

It is claimed that the first run under the new management of the Ranchita mine, near Banner, resulted in a cleanup of $50 per ton. The ore was taken from the 450 level of the mine. The quartz occurs in a series of lenses in mica schist.

The Golden Chariot mine, six miles from Banner, was the richest mine ever found in that region. It was shut down years ago and has never been reopened, though many believe, in these days of improved methods and machinery, that it would become a paying property if reopened.

L. M. Bailey is driving a crosscut tunnel to strike the vein of the Kentuck S., near Banner. The formation is mica schist and some of the ground very hard. A power drill is in use. This mine was quite extensively worked on the surface years ago.

A 5-stamp mill is being built at the Old Escondido mines, near Escondido, replacing the Griffin rotary mill formerly there. The Escondido mine has been worked off and on for many years. It is a fissure in granite.

San Diego *Sun*: Receiver C. W. Pauley of the Golden Cross mines at Hedges has filed his fourteenth monthly report in court. The cleanup of the 100-stamp mill for December was $30,796.60, and $1086.99 was received from other sources. The payroll for the month was $8000, fuel cost $800, and the current expenses amounted to $8000.

Shasta.

(Special Correspondence). — The German Co. reported "receiving bids for a smelter" is not at Kennett, but at Stillwater. The representative is Geo. Bayha of Redding.

Stillwater, Cal., Mar. 4th, '99.

(Special Correspondence). — The Golinsky group of copper mines, including the Ferguson & Goss properties, comprising nine claims and 160 acres, which were bonded in January last for one year to Lewisohn Bros. of New Jersey, are undergoing development under the supervision of W. R. Kemp, employing thirty men. They are running tunnels and sinking shafts. The formation is porphyry, the veins having a gossan capping. The deposits are so large that they can scarcely be called veins. The property is four miles northwest of Kennett.

A company of New York capitalists is developing a group bonded from Salitzer & Co., also near Kennett, which comprises a section of R. R. land and numerous additional locations. A large force is at work. This is known as the Mammoth mine.

The Balakalela and Windy Camp group of copper properties is under development by C. A. Malm and others of San Francisco and New York. In this group are above twenty claims.

Friday & Lowden are developing a large area of copper country, and their ore carries a fair percentage of gold. Northwest of these lies a gold belt in which are the Clipper & Snyder, the Uncle Sam and the Riley mines, all of which have been dormant for some time. The Uncle Sam was recently bought by Daken & Newcome from the Sierra Buttes Co. On this property twenty-five men are at work.

On Backbone creek, Chas. Butters has put in order his water plant and built a four-mile ditch 6 feet wide and 2 feet deep. He contemplates installing an electric plant and putting in an experimental cyanide station.

The Herrin group of seven copper claims is being developed by tunnels and surface cuts. The ledge is 9 feet wide. The lowest assay ran 2½% and the highest 10% copper. The property is under option to New York people.

Smithson & Graves recently bonded a group of copper claims near Kennet to an Eastern company who are pushing development work with a large force.

The Stowell property, a large area of copper territory, is being developed on an extensive scale.

There is little if any unlocated mineral land in this section and there is consequently no inducement here for other than capitalists. The outlook for the investment of large capital in the several properties named and the building of smelters is practically assured from the successful results thus far attained in the work in progress.

Kennett, March 6th, '99.

A strike has been made in the Black Spider mine. Ten tons of ore it is reported returned $8000. The mine is near Keswick. About a month ago the owners started in to do their assessment work for '99. They were about to leave the claim, having done the $100 worth of work when they struck the rich pay streak.

Shattuck & Thompson have located eight claims since Christmas on the hill west of Keswick. They have shipped to the smelters 100 tons from the Home Run and the Much in Sight.

A deed was recorded February 25th in which O. O. Howard Jr. made a transfer of the Mount Shasta mine properties, including the Mount Shasta, Lucky Boy, El Chiquita and the Anglo-American quartz mines, to the Mount Shasta Gold Mines Corporation.

Free Press: The Dry Slide mine, owned by D. McCarthy of Keswick, between the smelters and mine, is shipping rock to the Keswick smelters which samples $365 a ton.—— J. Scranton has struck ore in his mining property on Nigger Hill.

Stanislaus.

A suit for $23,000 damages has been filed in the U. S. Circuit Court by the Huron M. Co. against the Turlock irrigation district. The complaint alleges that a dam in the Tuolumne river belonging to the defendants gave way in July, '98, preventing the plaintiffs from carrying on their mining operations in the bed of the river.

Tuolumne.

At the Turner Flat gravel mine, near Montezuma, the new shaft is down 25 feet. It is located 1400 feet north of the old shaft.

The long crosscut tunnel at the Hazel Dell mine, seven miles northwest of Soulsbyville, has reached the vein 450 feet from the mouth and 250 feet below the surface. The vein is 2 to 2½ feet wide. Drifts have been started.

The Purdy vein, near the Hazel Dell, is opened by a tunnel from which six tons shipped to Selby gave satisfactory returns. W. B. Moore of Sonora, formerly Supt. of the Draper, is president of the company and L. B. Doe Supt. A 10-stamp mill is contemplated.

It is rumored that the Belle mine, near Tuttletown, will be started up again. The vein is big and has been sunk on 400 feet.

Sinking in the Excelsior shaft, near Sugar Pine, continues at 4 feet per week. The company contemplates putting in machine drills.

Two large boilers are on the road to the Lost Fox mine, near Sonora.

The second three-drill air compressor has been set up at the Alameda mine and will soon be in operation. In the north and south drifts on the 900 level they run 4 feet daily in each.

At the Accident mine in Big Oak Flat a new hoist will be set up.

At the Longfellow mine, on the north side of Big Oak Flat, an air compressor is being placed in position.

At the Jumper mine, near Stent, steam power has been introduced owing to unreliability of water power.

W. P. Scott & Co. of Soulsbyville will develop the O. P. quartz mine on the Comstock ranch, ten miles east of Columbia.

At the Republican mine at Jacksonville sinking has been discontinued for the present, work being concentrated on the 200 level, where drifts are being run north and south. The ledge has an average width of 15 feet. The 10-stamp mill on the Mammoth is making a run on rock from the Republican, which latter has a six-drill compressor operated by air transmitted 3000 feet by pipe from the Mammoth mill. The mine is working eighteen men, Jas. Haggin Supt.

Santa Ysabel recently declined to 9½ from 17. The bursting of the main water supply pipe, which leads from the reservoir to the company's mill, only necessitated the temporary closing down of the mill, and was not at all serious. The installation of electric power is contemplated.

Curtis & Anderson have a 2-foot vein near Columbia which shows free gold.

The Enterprise mill, on Bald mountain, is treating custom ore.

Rich rock has been struck in the Arbona mine, at Tuttletown, in the lowest level.

Promising ore has been found in the Alameda mine. Coal is now being used as fuel to run hoist and mill.

A new air compressor has been put in at the Norwegian mine, near Tuttletown, and sinking is in progress.

The Hennessey mine, at Saw Mill Flat, has been started up again.

In Five-mile creek district a pocket estimated at from $900 to $1400 has been found while grading for a 5-stamp mill, to be erected by the Mt. Lily Co. While digging out for the mortar block, a blind vein was discovered with the above results.

Independent: The suit of the Gerrymander M. Co. against the Golden Gate M. Co., was dismissed in the Superior Court at the request of the attorney for the plaintiff. The suit was brought against the Golden Gate Co. for damages for ore alleged to have been mined from the Gerrymander's ground.——Twenty feet of water is reported in the Tuolumne Co. Water Co.'s new reservoir, due to recent thaws.

COLORADO.

CHAFFEE COUNTY.

Whitehorn *News*: The Gold Bug at Turret is taking out of the drift some $150 ore which is being sacked. The streak of high-grade ore is about 3 inches wide with 20 inches of low-grade quartz.

CLEAR CREEK COUNTY.

At the Hudson mine a shaft house will be built and a hoisting plant installed near Idaho Springs. The property has been secured under lease and option by the Delta-Hudson M. Co. The shaft will be sunk to a greater depth; levels will also be driven. The streak of ore is several feet wide. This is the mine that was worked by "Brick" Pomeroy several years ago.

In the bottom of the shaft on the Dictator mine at Lawson, Van Housen & Co. have a streak of talc that runs $150 a ton. They are sacking it after drying.

The Silver Horn mine on Ute creek has been leased and an option given to a Denver pool for the working of this and other claims of the group. Some high-grade mineral has been produced and is now showing in an adit.

The Clear Creek Power Co. has made a number of purchases of ground along the creek below Idaho Springs and above near Empire. The main plant will be installed at Dumont, where ground has also been acquired. It is the intention of the company to supply

electric power to the mines of this and Gilpin county.

The Gem Extension, Main Trunk and Santa Fe mines are consolidated under one management. The Gem Extension is down 560 feet, and six levels have been driven on the vein, running from 300 to 700 feet in length. In all these levels there is good ore. The property is worked by leasers.

Republican: A strike is reported at Idaho Springs in the Shakespeare tunnel.——In drifting east of the Prosperity they came upon a solid streak of smelting ore. Alongside it is quartz, which also shows good values. The smelting ore runs 86 ounces gold and 283 ounces silver. The quartz runs 14 ounces gold and 100 ounces silver to the ton.

DOLORES COUNTY.

McCombe & McCarthey of Leadville will operate the Union-Carbonate mine, near Rico, under bond and lease.

EL PASO COUNTY.

Denver *Record*: Shipments from mines controlled by Woods Syndicate for the past week aggregated 950 tons, made up as follows: The Gold Coin, 90 tons a day; the Wild Horse, 25 tons a day; the Deadwood, 10 tons a day.

GILPIN COUNTY.

A contract has been let to sink 100 feet in the Delaware mine in Russell gulch, which will make that shaft a depth of nearly 650 feet when completed.

At the Theodore mine in Illinois Central district the shaft was recently sunk to a depth of over 300 feet, and while a good body of ore has been uncovered, it is of too low grade at present to stand the heavy shipping charges. Drifting is in progress.

A contract has been let to sink 100 feet on the Prompt Pay in Russell district, by Aspen parties. The shaft is down 140 feet.

At the Susan Mary in Lake district the shaft is down 215 feet.

At the Chemung-Belmont on Bobtail hill the owners are driving the east 240-foot level with ore in sight and also sinking a winze from the 180 east level to the 240 level in ore. An upraise is being made from the 90-foot west level to the surface for air.

In the Topeka mine there are from 600 to 700 tons of ore ready to hoist. The mine will be started up as soon as the weather justifies such course.

Twenty men are at work on the Running Lode near Black Hawk on the leasing system. Considerable ore is being taken out which will be shipped as soon as the roads are open.

Work on the Mountain City mine on Mammoth hill has been resumed and the pool expects to continue operations steadily.

Ore haulers near Black Hawk have been unable to keep the roads open lately and many mines are accumulating ore or are idle as a consequence.

It is reported that a good strike has been made in the Plateau

The Centerville No. 1 claim, located in Moon gulch, Union mining district, has been sold to Cripple Creek parties, who were represented by M. P. J. Gill.

GUNNISON COUNTY.

(Special Correspondence).—Things seem to to be somewhat quieted down at the Vulcan mine since the arrest of fourteen of the union men, who are now in the county jail awaiting trial, presumably on several charges. They will likely have to answer to the charges of trespassing, conspiracy to destroy the mine with explosives, making the Supt. a prisoner for a number of days, interfering with the mails, and for the shooting of one man. It is understood to day the men will not have a hearing before next week. From a man who was on the ground I learn that the men who were in arms and did most of the duty in arms are men who do not belong in the camp at all, and must have come from a coal camp named Baldwin, about seventy-five miles from the Vulcan mine. Mr. Davidson's report of the matter is not yet at hand. He has charge of the Vulcan mine.

Report has just been received that a snowslide has occurred at the Magna Charta mine, about thirty-five miles from Gunnison, in which six lives are reported lost. It is said the boarding house and bunk houses were swept away. The snow is packed in 150 feet deep and it will be several days before full details can be had. The mine is equipped with a large steam plant, also an electric plant and large double compressor and good buildings. It is hoped the machinery has escaped, as it was pretty well protected against slides.

Gunnison, Colo., March 3rd, '99.

A snowlide at White Pine on March 3rd killed six persons.

A contract was recently let by Mgr. Holmes of the Venable mine at Gunnison for sinking the shaft an additional 350 feet, making a total depth of 510 feet. A power drill plant of three drills capacity has been ordered.

News: The rich strike in the Goodhope mine, with the Vulcan mine, demonstrates the richness of the Gunnison gold belt. The ore was encountered in the 220-foot level 40 feet from the shaft. Nine assays averaged $800. Two men stoped down and took out about ten tons in one day.

HINSDALE COUNTY.

Lake City *Phonograph*: A strike is reported from the Clara L. mine at the lake. It was made at the junction of two drifts, in an accidental manner, while blasting to make a larger turn for the car.

Supt. Dinsmore has commenced work on the Yellowstone mine with five men.

Ten mining claims and a mill site in Sneffels district were purchased recently by A. E. Reynolds for $14,500. None of the claims are developed.

LAKE COUNTY.

Leadville has been snow-bound for several days. Snowslides in various parts of the State are reported.

The condition of the workings in the mines under Leadville is better than was anticipated, and it is thought that within thirty days after the bottom is reached all of the principal producers of the district will be in active operation. Most of the companies in this territory are making arrangements to work. The Home M. Co., which has had charge of the unwatering operations, will work the Penrose and Bon Air shafts, and their lease of seventy-five acres on the Starr placer. The Bohn shaft will resume at once; the Weldon is ready to go to work on repairs as soon as it can do so.

The lessees of the Castle View shaft on Carbonate Hill, Leadville, shipped 3000 tons of sulphide ore during February, it is said, at a net value of $15 per ton.

Shaw & Webb of Leadville have taken a six years' lease on a copper property near Salida.

The Banker M. & M. Co. has made preparations to commence sinking another lift in the Banker shaft at Leadville.

Miner: The Leadville Pumping Association had the water out of the stopes above the main working level in the Penrose shaft early this week. The workings exposed so far show them to be in better condition than was expected. The Northern shaft will be the first to produce ore. The Sixth-street shaft workings will soon be dry, and Mgr. Osgood will then commence operations.

MONTROSE COUNTY.

The copper mines at Paradox valley, in the La Sal mountains, are described in the Denver, Co!., *Post* as follows: "The vein varies from a narrow seam up to 24 inches, carrying silver and copper. It is a red sandstone sedimentary formation and the values come in what might be called porphyritic conglomerate on the surface. The whole country is impregnated with these veins and while they may be only stringers, the principal mine seems to be on a strong vein which is being systematically developed. No stoping is being done and the shipments made have been of ores that were taken out in the necessary dead work. There is a 600-foot tunnel and two shafts, one being down 90 feet, the other 50 feet. The company is shipping ten tons per day to the Argo smelter of Denver. Thirty four and six-horse teams are hauling this ore to Placerville, the nearest station on the Rio Grande Southern railway. It is eighty-two miles from the mines and it costs $19 per ton to transport the ores to the railway. The mines are fifteen miles east of the Utah line, at an altitude of 5600 feet, on La Sal creek, and are 100 miles from Montrose."

OURAY COUNTY.

The Atlas mine sends news of the discovery of a new bonanza on Mt. Sneffles. The drift is in 150 feet. A few weeks ago the mine shipped forty-five pounds of gold that was picked from the ore left on the dump at the close of the season. There is a free-milling streak in the mine 2 to 3 feet wide which averages nearly $20 a ton, and the rich shipping streak about 8 inches wide runs about $100 to the ton. The company will erect a reduction plant as soon as the most economical method is ascertained, as the ores vary in character and the company wishes a process that will treat the entire product.

PITKIN COUNTY.

Aspen *Sun*: An underground trolley line operated by electricity is now working between the Mollie and A. J., over which run ore cars half a mile. The system employed is the same as that used by street car lines and it is said to work to perfection. The saving is considerable when it is necessary to handle large quantities of low-grade ore, such as is being treated at the Mollie mill. It is only by such methods that the silver mine manager can profitably work his property under the prevailing conditions of the silver market.

SAN MIGUEL COUNTY.

Telluride *Journal*: G. Rohwer, developing the Sunshine group near Ames, recently broke into a streak of quartz from 6 to 8 inches thick that is full of ruby and brittle silver. It runs from 400 to 500 ounces in silver per ton. The whole Sunshine vein, 5 feet wide in the breast, is good milling ore.——The Enterprise mine at Rico is now giving employment to 125 miners.——What is wanting at Rico is a big milling plant that will successfully concentrate the low-grade ores, and it is practically certain to be built the coming summer.— The strike in the Rock Island at Ophir, made a week or two since, continues to improve. The ore body is now 10 feet wide, free-milling ore that mills $15 per ton in gold.

The *Examiner* says most of the working force of the Carribeau has been laid off while repairs are being made on the mill, injured by the snowslide (referred to on page 257). Some additional machinery will be added when the vanners are repaired.——Another shipment will soon be made from the Attica.

IDAHO.

A stock company is being organized in Spokane, Wash., to operate the Morgan City claim in the Buffalo Hump country. This claim is within 1500 feet of the Big Buffalo. A ledge ranging from 5 to 8 feet in width is traceable for a distance of over 600 feet, having been opened up in several places, and a 10-foot shaft sunk at one point.

A Spokane corporation has been formed to operate in the Buffalo Hump camp, and is kown as the Yankee Girl M. & P. Co. The company owns the Yankee Girl and Eureka claims, about two miles south of the Big Buffals group. The property is so situated that a tunnel run upon the ledge will gain a depth of 500 feet in running 700 feet.

There is a rumor of resumption of work on the Gem mine, in the Cœur d'Alene.

It is reported that 3 feet of solid galena have been uncovered in the Fourth of July mine at Hailey. At one side of this is 12 inches of lead carbonate.

Spokesman-Review: W. D. McFadden, who has returned from Buffalo Hump, says: "No work is being done upon the Big Buffalo at present. When the deal was pending three crosscuts were run across the ledge and then the work was stopped. These crosscuts showed the presence of an immense body of ore, the ledge at one point being 41¼ feet between walls. It is expected that work will be resumed upon the Big Buffalo in a few days. The road from Badger is probably now completed, and the 10-stamp mill which the owners of the Big Buffalo have purchased will be set up at the mine in a short time. The entire Hump country is now covered with between 14 and 15 feet of snow, and it is foolish for anyone to go in there with the expectation of prospecting. The tunnel on the Jumbo is being run on the hanging wall and the ledge is crosscut every 50 feet. A tunnel on the Elberton is in between 50 and 60 feet. The ledge is 12 feet wide, with a 5-foot pay streak. There are only thirty people in camp."

Spokane *Review*: The work which is to begin upon the properties of the Idaho Con. M. Co. will be in charge of G. O. Walker, who has been in charge of the Sacramento mine, at Mercur, Utah. The properties of the company are in the Buffalo Hump district.

Mirror: A distinct earthquake shock was felt at Mullan a few nights ago. The shock was so severe the men at work in the 1500-foot level of one of the mines quit work. In the town it was thought a terrific explosion had occurred in the Tiger mine.

MICHIGAN.

The annual report of the Tamarack M. Co. shows a steady reduction in the cost of treating the rock. In '97 the company cheapened its cost of stamping per ton by 3¾ cents as compared with previous year and '98 shows an improvement of 4 cents over '97. The total cost per ton mined was $1.94 in '96 and $1.66 in '98, and the total cost per ton stamped has been reduced from $2.28 in '96 to $2.01 in '98.

The report of the Quincy Copper M. Co. shows a surplus of $18,103 for '98 against a deficit of $107,282 in '97.

The annual report of the Osceola Copper Co. for the year ending Dec. 31st, '98, shows an increase in output of $211,764. During the year dividends to the amount of $277,250 were paid, being an increase over the previous year of $33,639. In his report to the directors Supt. W. E. Parrell says: "The cost sheet gives concise detail of the cost of mining and treating the rock mined, together with the cost of construction, which alone is no small item. Rock mined for the year, from all branches, 637,603 tons; rock stamped for the year, from all branches, 505,008 tons; mineral obtained for the year, from all branches, 15,848,928 pounds. The cost of stamping was 28 94-100 cents per ton. This, you will notice, is in excess of cost of stamping the previous year by about 3 cents per ton. The principal cause of this increase lies in the fact that for nearly six months the coal used at the mill was what was saved from the fire at the Dollar Bay coal shed, and was much reduced in steaming quality. At the stamp mill the sandstone tunnel has been completed and has a suction supply well in the rock for the new pump of 40,000,000 gallons capacity, now being erected, to supply water to all the mills. The pump house is a combination of stone and steel. The stone foundation walls are 24 feet deep, on which are added 16-foot posts of structural steel, the floor space being 88x45 feet. The building is completed and the pump is being installed. The new stamp mill building is of steel. In size it is 215x135 feet and designed for three 20x24-inch cylinder heads. In many respects this new mill will be a departure from the old types in its operations of stamping. Mill machinery is being received and put in place, and if no unusual delays occur in the balance yet to be received the 1st of July ought to see the mill completed."

MINNESOTA.

Vermilion *Iron Journal*: One of the most promising veins of gold quartz that has been discovered in this section has been recently located. The vein is reported as averaging 22 feet in width and is traceable on the surface for a distance of nearly a mile. Various assays have been made from quartz taken from different portions of the vein, showing a richness of about $24 to the ton.

MONTANA.

All negotiations for the purchase of the Parrot by the Standard Oil Co. have just been broken off. The Standard Oil Co. offered $30 per share. Men who had options on 156,000 shares offered to sell at $40 and finally at $36, which was refused. Last year the Parrot Co. earned $750,000 net on a 15,000,000-pound copper output, or about $3.20 per share on its 230,000-share capital.

The Anaconda Copper Co. shipped last week ninety-one silver bars valued at $90,000.

B. F. Penn and O. S. Brooks are working the Standard mine, on Wisconsin creek, opposite Leiterville. They have out about twelve tons of ore ready for shipment.

The Revenue mine, which adjoins the Legal Tender at Bear Gulch, is being developed by the Bear Gulch M. Co. with a force of twenty men. The mill will be enlarged to eighty stamps.

The Levi Burr mine, at Hasmark, is shipping high-grade ore. A tunnel 20 feet long has been driven on the lead and work is in progress to connect it with the shaft.

The sale of the Colorado Smelting & Mining Co.'s property at Butte, Mont., to a New York company is announced, the price being $2,500,000.

The claims of the High Ore Gold & Copper M. Co., six miles from Boulder, are under lease to Orwell Bros. & Sanders, who are working in the tunnel, which is in 2000 feet. They have a 2-foot lead of ore, from which they are about to make their first shipment.

A steam stamp mill is being placed on the Mantle mine, near Basin.

At the Snowshoe mine the main tunnel is in 1260 feet. The crosscut tunnel is now in 135 feet, and it is expected that the ledge, which on the surface is parallel to the main lead, will be encountered in a few days.

A dredge, having a capacity of 3000 cubic yards per day, is being designed for the placer mines of Horse Prairie. It will be operated by the continuous-bucket line and will cost $40,000.

Missoulian: The Frazer & Chalmers Co. are figuring with the Snowshoe M. Co., in the Libby district, for a 500-ton concentrator, to be erected this spring. There is now a 100-ton concentrator on the property that has been in operation for some years.

NEVADA.

The enormous pressure in the discharge pipe at a point 5 feet above the turn in the pump in the C. & C. shaft on the Comstock occasioned a breakage several days ago. The Risdon Iron Works, in anticipation of such possibility, had a duplicate of phosphor-bronze which replaced the broken funnel-shaped joint of the discharge column that couples on the injector. Defects in construction are often found in work of any magnitude as it progresses and are to be remedied and obviated as they arise. Upon arrival the new piece was fitted and found satisfactory. Some other changes are required which will require a temporary cessation of all pumping operations. In future work sections of 150 feet each will be used instead of 50 feet, as heretofore. The report from the Con. Cal. & Va. mine for the past week states that the C. & C. shaft for 50 feet below the 1750 level has been cleaned out and repaired and the pump rod column, piping and stays have been taken out of the pump compartment. From the 1750 level down this compartment will be repaired so that the pump cage can be used for all work on the pumping plant after it has been installed, as during the installation they have to use the center hoist compartment. On the 1400 level the drift has been cleaned out and retimbered and track laid for a total distance of 264 feet. Work has been resumed on the 1750 station and has been continued on the electric installation.

On the Comstock the Kinkead M. & M. Co. is extracting low-grade ore fillings from the upper workings of the Gould & Curry, paying the G. & C. Co. a royalty of 10% on the gross bullion returns of ore milling $10 or less per ton. On the gross bullion returns of ore milling $11 per ton the G. & C. Co. is to receive 11%, and so on.

It is reported that well borers sinking at Cradlebaugh's at a depth of 150 feet struck a flow of 7 miner's inches of water.

The Golconda *News* says that there will be an electric car line from that place to the Adelaide copper mines in the near future.

Virginia *Chronicle*: W. H. Kent, who has a mine near Silver City and interested in Jumbo district on the west side of Mount Davidson, claims to have discovered a fissure vein in that district. He says an old tunnel in that vicinity barely missed cutting the point of contact, the men having followed an ore stringer which led away from the main fissure. By extending this tunnel in an opposite direction the point of contact of the main fissure was found and disclosed a wide vein of gold-bearing ore, the trend of which is from northwest and southeast. The fissure has well-defined walls with a heavy clay, 22 feet in breadth.

Virginia *Chronicle*: The sulphur properties in Humboldt county are being actively worked by a St. Louis firm.

NEW MEXICO.

On the 27th ult. was organized at Elizabethtown the E'town Tunnel Co., which has secured a concession from the Maxwell Grant Co. to tunnel old Baldy mountain crosscutting the formations.

At White Oaks the cyanide plant at the Old Abe mine has been completed and a test of the tailings piled up on the dumps made, which is reported satisfactory. The plant contains six tanks, each of which has a capacity of fifty tons.

At Bland the Cochiti G. M. Co. is taking from the third level rich ore.

The new mill of the Timber Peak M. Co., at Walter canyon, will be finished April 10th. The company controls twenty-six claims; the development work consists of 2000 feet of shafts and tunnels. The bank blasting system will be adopted in mining. Shafts are to be sunk 75 feet and small crosscuts run, in which will be placed from 5000 to 10,000 pounds of powder for each shot. The blast will raise 8000 tons of ore. It is locally figured that the cost of mining will not exceed 20 cents per ton. After blasting the ore, it will be shoveled into a derrick scoop and swung into cars of five tons capacity. The ore is porphyritic in character and the major portion of the values are found in the iron sulphides. Where the ore is decomposed or oxidized, free gold is frequently found. The mill will have a daily capacity of 150 tons.

The mines in the vicinity of Hillsboro, says the *Advocate*, have produced 2565 tons of ore since Jan. 1st last.

Hillsboro *Advocate*: A strike has been made on the 7-20 mine, at Hillsboro, by Wayland & Martin. The vein is 15 inches wide and the ore assays $120.——The Warren mine is in bonanza. ——The Opportunity leasers number fifty-eight, and they are all making more than $3 per day.——P. M. Porter, owner of the Snake and Opportunity mines at Hillsboro, is about to build another mill in order to handle the increased output of these properties.——The Richmond mine has again increased its force; there are now ninety-seven miners employed there.

OREGON.

At the sheriff's sale of the Hammersley mine at Grant's Pass the property was bid in for $2675.

Phillips & Stevenson are developing copper claims south of Waldo.

Sholtz & Cagle have a rich seam on Sharp's gulch, from which one week's panning netted $300.

Burlison & Booth are working the old Indian Girl property near mouth of Ash creek.

A brick of bullion containing 1360 ounces of gold valued $22,000, the results of the free

gold cleanup for February of the Bonanza mine near Baker City, was deposited in bank at Baker City by A. Geiser, Mgr., a few days since. There are also thirty tons of concentrates, valued at $5100, and one car of ore sacked for shipment to smelter, which is worth $10,000. The Bonanza and Columbia mines are sacking their richest ore. The Columbia has sold two cars of ore on track in Baker for a large sum.

F. A. Stewart, during the month of January, took out $500 from his beach mines. When the tide would become sufficiently low to permit of work, Stewart and his men would carry their machine down, set it up and shovel in the sand until the encroaching tide would compel them to pick up their machine and carry it above high water mark.

The Exchange and Paymaster mines, seven miles east of Baker City, discovered last fall, are reported to have made rich strikes. The Exchange shows an 18-inch vein, a 6-inch stringer, which has been found to be rich. The Paymaster has a 4-foot vein, on which development work is being pushed.

It is reported at Cornucopia that the deal for the purchase of the Cornucopia mines, of which H. A. Shippman is Mgr., to Youngtown, Ohio, capitalists is off. Improvements are to be made on the Last Chance and Red Jacket mines. It is proposed to put in an electric plant on Pine creek, construct a tramway and run many hundreds of feet of tunnel for the development of the mines.

The Minetta B. hydraulic mine, in the Happy Camp district, is working.

E. C. Palmer is putting in a MacArthur-Forrest cyanide plant to work 5000 tons of tailings from the Jilson & Roberts mine near Hornbrook. The plant will be of thirty tons per day capacity.

A cyaniding plant having a 25-ton capacity daily is in contemplation at Grant's Pass.

At the Ibex mine, near Sumpter, fifteen men are at work, drifting on the ledge, crosscutting, building the necessary houses, and otherwise employed.

The new $100,000 mill at the Golconda mine, near Baker City, is nearing completion. In this mill the bromo-chlorine process will be tried on a commercial scale.

The Baker City *Democrat* hears that the Bonanza mine management will increase the present 20-stamp mill to 100 stamps; A. Geiser is Mgr.

Near Baker City, the Elkhorn M. & M. Co., F. Pfau, Mgr., is arranging for increased development of the properties.

SOUTH DAKOTA.

A new steam hoisting plant has been purchased in Denver, Colo., for the Gold Coin mine, near Custer.

Sinking is in progress at the Sunny Side mine, near Hill City.

The cyanide works at Spearfish are in operation again, for the first time since the cold weather set in. During the lay-off new elevators have been put in and various other improvements made.

Messrs. Bowe, Cheeseman, Martin and Bartell, who own the Waco group of gold claims, near Hill City, will build a mill on the property.

UTAH.

Good finds have been made in the old Delker district in Butte valley near Elko. Rich copper ore valued at $50 per ton and ore assaying $14.50 in gold have been found. There is a large body of copper ore in the Emma claim.

The pumice mine near Black Rock shipped twenty-five cars to Chicago last year and is now shipping a car each week. Three men are employed in quarrying and sorting pumice. Mining and loading on cars costs $2 per ton.

Twenty-nine inches snow (rain measure) is Utah's February record. The greatest fall during any other February of which there is official record was 18.8 inches, in 1893.

Mgr. Daly of the Daly-West at Park City has resumed work with a full force.

The Tesora M. Co. last week made final payment of $10,000 on its property near Silver City, Tintic district.

A snowslide at Alta, at the head of Little Cottonwood canyon, on the 1st demolished the buildings of the camp. The slide started at the Flagstaff mine on the mountain side and swept down into the canyon. The Emma mines and some of the best buildings in the camp were directly in the path of the slide and, it is stated, they were all crushed.

Standish & Jimpson have secured a half interest in the Rogers mill and will increase its capacity to forty tons. The building is to be enlarged and supplied with new machinery. The new outfit will be known as the Rogers M. Co., with J. B. Rogers Mgr.

After lying idle since December, the Old Jordan and Galena mill has started on a several days' clean-up, when it is to be thoroughly overhauled and repaired.

Mgr. Bruback of the Herschel mine, at Mercur, has added another shift to his forces.

B. Sprenger has been at Stateline arranging for the resumption of work at the Ophir and other properties, upon which he recently procured an option.

The lessees on the Old Telegraph, at Bingham, have several hundred tons of copper and gold-bearing ore on the dump that will reach the market with the opening of the roads.

The management of the Snow Storm mine, West Dip, after an expenditure of over $5000 in exploring the ground, have run into a good-sized body of pay ore. A drift being run north about 30 feet from the main shaft on the 300-foot level broke into a shoot that carries $3 80.

The Jumbo claims, seven in number, are being developed under the direction of W. Bailey, who has a force of men at work. An incline is being driven on the vein and an excellent showing is being made. Values as high as $12 have been found, but the general average is $3 and $4.

The refinery at the Manning mill, at Mercur, is well under way.

A smelting plant is proposed, which will probably be built in the Jordan valley on the site of the old plant of the Telegraph mine. P. A. H. Franklin of Salt Lake is largely interested in the enterprise.

In the Lower Mammoth at Tintic the drift running north from the No. 5 level has broken into a full face of ore heavily copper-stained and showing a fine quality of galena. The territory from which the strike is reported has never been explored.

There is considerable activity on the South West-Dip around the hill from the Sunshine in Camp Floyd district, with encouraging results. At the Sindar the shaft is sinking on a new vein that is from 11 to 15 feet between walls.

The Daly-West at Park City has again resumed work with thirty-five men. When this force has gotten things in shape a much larger number will be employed.

A number of new finds are reported from Bingham, made by prospectors during the winter.

Tribune: The Bullion-Beck of Tintic last year produced and marketed 19,260 tons of ore, and distributed $90,000 among its shareholders. The workings of the property have now attained a depth of 1400 feet, at which point a gratifying body of ore is exposed; 120 persons appear upon the payroll. The regular meeting of directors will take place March 10th.

Bingham *Bulletin*: The lower tunnel of the Fortune group is now in 1600 feet. For a long distance it has followed a good ore streak that is "in and out" and carries copper. A raise of 1500 feet is up 70 feet, and not a pound of waste has come from it. The Keystone level, 100 feet above the Fortune, has been driven 1100 feet along footwall. A raise in this level near its face shows an 11-foot ore body.

WASHINGTON.

A $15,000 smelter is to be built on the Uncle Sam mine near Bossburg east of Republic.

The Princess Maud mine at Republic is now showing the granular white quartz that is characteristic of the Republic.

Work has been resumed on the El Caliph shaft. It is expected that the shaft will reach the tunnel level about the time the tunnel reaches the vein.

Three cars of ore have been received at the Northport smelter from the Second Relief mine near Erie, B. C. There are sixty-five tons in the shipment, which had a customs valuation of $41.20 per ton. This claim is owned by Finch & Campbell of Spokane.

On the Aspinwall at Republic the vein is stripped and exposed 6 feet across. The ore is a soft, bluish porphyritic quartz, resembling the ore which is now being taken from the Republic mine.

Thirty-five mines are in operation within three miles of the town of Republic, giving employment to 500 men, the Republic having 250 men on its payroll. The Mountain Lion is putting in a boiler and machine plant.

At the Castile mine the shaft is down 160 feet, following the lead, which is 8 feet between walls, the entire bottom being in ore. At a depth of 200 feet the ledge will be crosscut. The Castile is within a mile and a half of the Le Roi smelter.

Between 200 and 300 men are working in the Pierre Lake district, engaged in the development of claims and in prospecting.

The Queen of Sheba claims—the Queen of Sheba, Rose, Philadelphia and Montana—are eight miles east of Bossburg. The shaft on the Queen of Sheba is down 50 feet on an 8-foot ledge of ore. Six men are employed. This group is owned by the Queen of Sheba G. M. Co., a Bossburg corporation.

Another strike of telluride ore is reported from the Flaghill claim at Republic, and of gold ore in the Bunker Hill mine, Palmer mountain, Okanogan county.

A 5-stamp mill is in operation on the Mountain Goat mine near Winthrop. It was taken in some time ago. At the first run of a week they took from the stamps four pounds of gold, avoirdupois, besides the concentrates.

On the Eureka, owned by California capitalists, men have been at work all winter and more men were recently added to the force.

At Golden Zone, Okanogan Co., one and one-half miles south of the international line, A. C. Kingsbury has the Golden Zone mine, on which considerable development—mostly tunneling—shows $35 per ton gold. He will put in a sixty-ton concentrator.

At the Ben Hur, at Republic, it is the intention to sink a shaft to a depth of 500 feet, thoroughly opening up the ledge at various points. The location of the shaft has not yet been selected, but it will be at once and sinking started within ten days.

The New York-Republic G. M Co. has been organized by Spokane and Palouse City men, to operate a group of copper claims two miles northeast of Republic.

The Gold Mountain G. M. Co. will develop the Ground Hog claim, which adjoins the Gold Ledge, at Republic.

The Pontifex G. M. Co. has been formed at Spokane, with a capital of $50,000, to develop the Pontifex group on the Colville reservation, northeast of Republic. A. W. Siegel is Pres.

Near Conconully R. R. Hargrove has completed a 225-foot crosscut tunnel and cut into the ledge 14 feet on the Hidden Treasure, and has not yet reached the foot wall, the 14 feet being all in ore. Two hundred tons of ore were taken out in running this crosscut. The ore carries silver, a small percentage of lead and some gold. It is the principal location of a group of five claims on Salmon creek, one mile north of Conconully. The crosscut was started 500 feet above the creek and attains a depth of 200 feet where the ledge was cut. Among others interested in this property are M. M. Cowley and N. Clark.

The Bullion group of mines at Flat Creek Camp, nine miles west of Northport, is owned by a Spokane company. The principal vein is said to be 45 feet wide. The owners are doing development work. A shaft has been sunk 100 feet and a crosscut run 45 feet toward the hanging wall, but work was abandoned owing to water. The company is negotiating for pumping machinery.

Northport *News*: At the Le Roi smelter nearly all of the men have been laid off. Only a few of the machinists, the engineers and a few other workmen have been retained. When the company will resume smelting can not be ascertained, and it is doubtful if the company knows to a certainty. Ore bins and sheds for the reception of ores have been enlarged and fully made ready.

Spokesman-Review: About 925,000 of the 1,000,000 shares of the Republic G. M. Co have been pooled for six months. The Republic mill is working steadily.——The Lone Pine Con. M. Co. of Spokane will build a mill the coming summer. P. Clark, who is largely interested, says it will be a cyaniding plant.

Spokesman Review: A strike is reported rom North San Poil. The strike was made at the bottom of the 20-foot shaft and the entire bottom of the shaft is now in rock which will average over $200 per ton. The assays made Saturday ranged from $272 to $800. It has been known for some time that this property had a rich ledge but nothing of this sort was expected.

WYOMING.

The Cox copper mine on Big creek near Rawlins has been sold to Boston investors who have made the first payment of $5000 on the property.

FOREIGN.

AUSTRALIA.

Experiments at the Broken Hill mines, N. S. W., toward the separation of a fair-grade zinc concentrate, have been made during the past year, but, so far, only comparatively small quantities have been obtained.

The Broken Hill Proprietary Co. of New South Wales has declared 120 dividends, aggregating £6,760,000.

The total amount of water consumed during January at the Broken Hill mines amounted to 16,497,000 gallons.

BRITISH COLUMBIA.

Z. D. Brown, Mgr. of the Bullion M. Co., will buy machinery for the property, four claims in Flat Creek camp on the reservation, nine miles north of Northport. The ore is extra rich galena.

Electricity is coming into use in Rossland. The Coxey, War Eagle and Iron Mask have each installed plants driven by electricity. It is said that the British America Corporation has under contemplation the substituting of electricity for steam on its several properties.

British Columbia has ninety-four mines that produced ore in sufficient quantities in '98 to pay the tax to the provincial government as required by law.

The Hall Mines Co. at Nelson is erecting a silver-lead smelter, and the Canadian Pacific railway has material at Trail and expects shortly to have its silver-lead stacks in operation. This will greatly reduce the cost of treating ore.

The Relief G. M. Co. is making regular ore shipments to the Northport smelter. Besides the shipping ore they are piling up milling ore at the rate of fifteen tons per day from development work.

Twenty men are at work on the B. C. mine at Greenwood. A fund of $50,000 is reported on hand for development purposes.

The Boundary Creek country in British Columbia, adjoining the Colville reservation on the north, is attracting attention. The Ironsides & Nob Hill Co. contemplates the erection of a 1000-ton smelter. There are now about 3000 men engaged in constructing a railroad from Rossland through that mining region.

The Green Mountain, near Rossland, is still adding machinery to its plant. Recently a compressor plant was ordered and last week a 60 H P. boiler was put in. The shaft is down 125 feet. It will be sunk to the 500-foot level. Lately some ore showing native copper was found.

The Rossland *Miner* predicts a lively rivalry between the electric company and the new compressed air company when the latter is ready for business. There will doubtless be found a field for both.

The Emily Edith has lately developed new ore bodies at greater depth, and a concentrator will be erected on this property.

The Canadian Pacific Exploration Co., Ltd., operating the Porto Rico mine, are about to run a tunnel, at the mill, 2700 feet long, to tap the ledge at a depth of 1200 feet.

On the Yellowstone mine, near Ymir, there are eighteen men at work.

The Payne M. Co. of British Columbia, Ltd., capital stock 1,000,000 shares of $2 50, has been listed on the Toronto stock exchange. The price quoted per share is $3 30.

W. H. Norris and J. Beckwith will crosscut the ledge on their claim, the Lygia, which is situated on Ingram mountain near Midway. Surface work shows a vein 40 feet wide, between walls of granite and porphyry.

The drift on the 300-foot level in the Cariboo at Camp McKinney is now within a few feet of the vein.

February's shipments of ore from Slocan mines make a total since January 1 of 6500 tons. In the year 1898 the total amount of ore shipped from the Slocan reached 17,000 tons.

The Noble Five mine near Sandon, which was closed down last year for lack of ore, this year promises to be one of the heaviest shippers of that belt.

In the Slocan the Payne mine is shipping 200 tons a week. The Last Chance is shipping 120 tons, the Idaho Mines 80 tons, the Queen Bess 60 and the Whitewater from 60 to 75 tons. Other shippers are sending out smaller shipments weekly.

The Salmon River & Porcupine M. Co. intend introducing diamond drills in the Ymir district; the first drill will be placed on the Flossie R.

At the Ymir mine, Ymir district, in No. 3 tunnel, where a station is cut, from the footwall to the hanging wall there are 30 feet of ore.

Work on the Waterloo mine at Camp McKinney was commenced October 3d, '98, since which time a shaft has been sunk 83 feet, in an ore body the entire distance, the width of which was never less than 6 feet, cutting three shoots of free gold. The first shoot was at a depth of 5 feet, the second at a depth of 25, and the third at 51 feet. All three dipped west at an angle of 25 degrees. The shaft is 7 by 5 feet clear, timbered to the bottom. The first level was started at 65 feet, leaving 18 feet for a sump. From a station a drift has been run 60 feet on a ledge 5 feet 8 inches wide. At 15 feet from the station another shoot of free gold was encountered.

Cœur d'Alene *Press*: A strike has been made at the 70-foot level in the Golden Eagle, on the north fork of the Kettle river, in the Boundary country. The find consists of 4 feet of high-grade copper-gold ore, from which assays were had from $50 to $100.

The Dundee concentrator, capacity 50 tons, has been running steadily for a month or more, and the product hauled to the railway. The ore thus treated is the second and third grades, and yields in concentrated form $40 per ton.

Victoria *Times*: The Annie M. (Little Cariboo M. & M. Co.) shaft is now down 50 feet in ore. Water is getting troublesome and a hoist and pump will be in order on this claim.

Nelson *Tribune*: A foot of ore has been struck in the drift being run on the Mabou, which adjoins the Enterprise mine on Ten Mile, Kootenay district. The finding of this ore indicates that the ore bodies developed in the Enterprise extend into the Mabou.——At the Get-There-Eli claim on Twelve Mile, Kootenay district, the whole face of the drift at the present time is in ore. In four shifts ninety-five sorted sacks of this ore was put up ready for shipment by two men.

MEXICO.

Two Republics: Whether or not the prospector or and discoverer of the mine stands as good a chance of realizing from the results of his labor as the subsequent purchaser and speculator, we take it, depends very much upon the man himself. It is usually a case of each side trying to get all there is in sight, and the best man wins. The prospector will wait until he sees the mine developed; if it turns out to be a bonanza, and he gets nothing, he feels that he has been robbed; but if the other fellow spends all his money and finds nothing, the prospector who comes forward and offers to stand his share of the loss has yet to be discovered; he is in that case a very scarce animal. If the mine is no good, we think there is a greater demand for capital to develop it than vice versa; but if the property be really first-class, the demand is the other way.

Many prospectors, it is reported, are going into the newly discovered placer fields situated about eighty miles south of Calmalli, Lower California.

The placer gold mined at Juarez in Lower California is worth over $20 per ounce.

There is some activity again in the mines of Alamo, Lower California, the scene of a stampede in 1887 88.

At Sierra Mojada, Coahuila, R. M. Rich has struck a vein 4 feet wide which assays fifty ounces silver and 3% copper to the ton.

The Cobato copper mines in Sonora are reported sold.

The litigation involving the title to the La Brisca placer mines, forty miles east from Magdalena, having been settled, the owners expect to begin work upon the property soon.

The Otate mine, in the vicinity of Llano station, has a new hoist and sinking in the shaft is progressing.

J. F. Johnstone of the La Cruz mine near Parral is sinking two shafts.

J. M. Botello has made a strike in both the San Joaquin and the Providencia mines near Parral.

NEW ZEALAND.

Mining Journal: The returns of the gold export for the past year show a substantial increase in the figures compared with the previous year. The total quantity exported in the year '98 was 280,175 ounces, as compared with 251,645 ounces in '97, and the value was £1,080,691, against £980,204. The output last year was thus 28,530 ounces more than in '97, and the value of the metal showed an increase of £100,487. The following is a comparative statement of the value of the production of the various provincial districts for the two years:

	1897.	1898.
Auckland	£392 337	£527,786
Marlborough	3 195	3,103
Nelson	7,655	6,882
West Coast	235,439	319,784
Otago	342,187	223,231

SOUTH AFRICA.

A Washington, D. C., dispatch notes a consular report from Cape Town which says that, reckoning on the basis of the September reports of outputs, South Africa will produce in the current year $76,647,375 of gold, which would place South Africa's gold product ahead of all other countries.

TASMANIA.

A correspondent of the New Zealand *Mining Journal* says: The returns of the last crushing of the Tasmania mine was 1370 ounces from 960 tons of stone—an average of 1 ounce 6 dwt. per ton. The year's crushing produced 20,955 ounces, valued at £91,567, from 26,370 tons, being about 18½ dwt. per ton, showing the mine to be of high-grade ore. Since its formation this company has won 443,167 ounces of gold and divided £679,071 in dividends. Another company, the New Golden Gate, yielded 5644 ounces amalgam (approximately 1900 ounces of gold) from 2380 tons of quartz.

Industrial Notes.

—The Arizona T. & L. Co. has completed a sawmill in Flagstaff, Arizona.

—The Lincoln, Placer county, Cal., pottery has shipped six carloads of sewer pipe to Manila.

—Express matter was in February sent in five and one-half days from Syracuse, N. Y., to City of Mexico.

—The Indiana Natural Gas Co. has placed an order with Pittsburg manufacturers for 150 miles of 10-inch iron pipe.

—The Santa Fe road is reported to have secured control of the California & Nevada road to establish the Oakland, Cal., terminal.

—The Puget Sound Sawmill & Shingle Mill Co., Fairhaven, Wash., in '98 cut 117,402,000 shingles, operating 292 days of the year.

—Officers' quarters at the Mare Island, Cal., Navy Yard, to cost $107,500, will be built by Sinnott & McCann of San Francisco, Cal.

—From numerous Eastern points iron and steel product manufacturers and cotton mills report a general advance in wages of employes of from 5% to 10%.

—At Bonners Ferry, Idaho, a portion of the Kootenay Valley Railroad workmen are on a strike for higher pay. They demand $2.20 instead of $1.75 per day.

—The total exportation of California wines to Europe in '98 amounted to 557,671 gallons, valued at $193,583. The bulk of this went to Great Britain and Germany.

—The British Columbia Government has passed laws to prevent the employment of Chinese and Japanese in semi-public works and in underground coal mining.

—Consolidation of the electric and cable street railway lines of Denver, Colo., has been effected under the name of the Denver City Tramway Co., capital stock $5,000,000.

—The aggregate appropriations of the recent session of Congress were $675,885,489. The total appropriations for the last year were $893,231,615, making a total for the Congress of $1,569,117,104.

—At Nanaimo, B. C., the Alexander strike is reported still on. The men say they will remain out until the Dunsmuirs increase wages 50 cents per day, same as standard wage paid by the New Vancouver Coal Co.

—The Santa Cruz, Cal., powder works employ 200 men. Ten thousand dollars is paid monthly in wages. The present daily output is 700 kegs of blasting powder and 6000 pounds of smokeless powder. All of the latter goes East.

—The transport steamer Valencia sailed from San Francisco on the 5th inst. for Manila via Honolulu, laden with supplies for the troops in Hawaii and the Philippines. She carries $1,500,000 in coin for the payment of soldiers.

—Mine owners of the Cœur d'Alenes, Idaho, are forming a company to generate electric power at Thompson Falls, Mont., to operate mining machinery in the Cœur d'Alenes. The power plant is to be located on an island near Thompson Falls.

—The Oregon Short Line is looking into the feasibility of extending its line from the northern end of its Montana division across the Bitter Root range into the Salmon river country, and thence into the Buffalo Hump district near Grangeville.

—The construction crews of the Nevada, California & Oregon Railroad have reached a point twelve miles north of Amadee, Lassen county, Cal., and are extending the roadbed across the Madeline plains toward Alturas and southeastern Oregon.

—The biggest sticks of lumber ever cut in Portland, Or., were cut at the mill of Inman, Paulsen & Co. last week. They were of fir and were 3 feet square and a little more than 48 feet long. They contained 5200 feet of lumber and weighed about 20,000 pounds each.

—Kilpatrick Bros. & Collins, railroad contractors of Newcastle, Wyo., have contracts for cut-offs to be made on the Union Pacific between Laramie and Rawlins. It is estimated that the work will require the employment of 2000 men and many horses and mules.

—Negotiations for the delivery of 30,000 tons of Leadville, Colo., manganese ore to the Illinois Steel Works at Chicago have been closed. This contract, with those now in force, assures the production of 60,000 tons of this class of ore in Leadville during the next ten months.

—The Northwest Railway Co. have let a contract to Orman & Crook of Pueblo, Colo., for grading twenty-eight miles of roadbed from near Huntington, Or., in the direction of Seven Devils district in Idaho. There are 200 men now at work, but the force will be increased to 1000.

—Baker City, Oregon, will supply water for domestic purposes and for its mills by a ten-mile gravity system, the cost of which is estimated at $110,000, for which the city proposes to issue bonds. This is the first instance on record in which the mills for ore treatment are supplied from a municipal water system.

—At Fresno, Cal., S. N. Griffith proposes to construct and operate an electric railway and extend it into the colonies adjoining Fresno, and, besides his passenger service, to run freight cars, enabling vineyardists and wineries to ship their produce to Fresno. If the idea is consummated, the San Joaquin Electric Co. will furnish power.

—Summerland, Cal., papers say that the entire production of the Summerland oil field has been sold for several months ahead. That condition of affairs has been brought about largely by the decline of the Los Angeles field. Considerable development work is in progress now and some good wells are being struck at various points along the beach. Work is greatly retarded on the beach by the uncertainty of the title to the tide lands adjacent.

—Pittsburg reports an advance of 50 cents a ton in steel billets and Bessemer pig iron. Billets are quoted at $23 per ton and Bessemer at $13 50. Under the scale agreement of the Amalgamated Association the advance in steel billets will be followed by an advance of 8% in the wages of the skilled workmen. The advance will affect about 15,000 men.

—Pasadena, Cal., is now lighted by electricity, transmitted from the head of the Santa Ana river, seventy-eight miles distant, the wires delivering at Pasadena 3000 volts. As the city uses ordinarily on the incandescent light service but 1000 volts, the current runs into a bank of transformers, is reduced to 1000 volts and transferred to the local incandescent wires.

—It is noted as a striking evidence of the development of the country that the St. Louis World's Fair in 1903 calls for as much money in city, county, state and federal appropriations as the entire Louisiana purchase cost in 1803. Fifteen millions of dollars was a staggering sum in those days, but it will be spent now as a matter of course in an educational festival to commemorate the centennial.

—At Dawson, N. W. T., Gold Commissioner Senkler has made an important ruling as follows: "A person locating a claim, and, after prospecting it, finds it a blank or unprofitable, he can make an affidavit to that effect and regain his right to locate again on unoccupied ground in that district. This is a very important concession, as heretofore a person lost his right after recording. Parties after completing their representation work must renew the lease before the year expires from date of recording. This point should not be overlooked to save the loss of the claim. All concessions for hydraulic and dredging purposes are obtained from Ottawa, this office not having the power to make grants."

Personal.

D. W. Ross of Boise is Idaho's new State Engineer.

F. MITCHELL is the new New Pass Supt., Austin, Nev.

MGR. NESBIT of the Bullion-Beck Co. is in Salt Lake, Utah.

H. PENGELLY is now Supt. Douglass mine, Volcano district, Amador Co.

J. E. POINGDESTRE of San Jose, Cal., has gone to Chicago for four months.

G. E. BAILEY is managing the Chloride-Bailey mine in Trinity Co., Cal.

J. F. MCDONNELL has been re-elected secretary Virgina, Nev., Miners' Union.

H. L COY has been engaged to take charge the Golden Lily mine at Republic.

J. B. HAMMOND of Portland, Or., has been inspecting mines in southern Oregon.

R. K. COLCORD has been confirmed by the Senate as Supt. of the Carson, Nev., mint.

W. A. FARISH has been making examinations of mining property in Bingham, Utah.

J. E. JACKSON has resigned the presidency of the Salt Lake City, Utah, Mining Exchange.

J. M. VAN COTT of the Murray Iron Works Co. of Burlington, Iowa, visited Denver on the 28th ult.

JAS. V. COLEMAN of San Francisco, Cal., has been at Angels, Cal., inspecting his mining interests.

J. J. FREY, Gen. Mgr. Santa Fe system, has resigned. It is thought that Chas. Dyer will succeed him.

FORREST KALDENBERG has taken charge of the affairs of the Live Oak Copper Co. at Globe, Arizona.

L. MCGAFFEY, formerly of Angels, is millman at the Crandall mine, near Auburn, Placer Co., Cal.

BYRON E. SHEAR of Denver, Colo., contemplates a trip through Arizona, where he has mining interests.

ROBT. S. MOORE, of the Risdon Iron Works, San Francisco, sailed last Thursday for the Hawaiian Islands.

CHARLES BUTTERS was in Denver on Feb. 28th, enroute to New York. He expects to make a trip to Europe.

DAVID A. BAUM of the Baum Iron Co., Omaha, Neb., recently visited his branch house in Denver, Colo.

PERCY WILLIAMS, formerly of Silverton Colo., is now superintendent of the Red Bird mine at Clayton, Idaho.

W. W. CHISHOLM, Treas. Centennial-Eureka at Eureka, Utah, has returned after an absence of several weeks in Utah.

J. B. HASTINGS, Supt. War Eagle mine at Rossland, B. C., has been engaged to examine the Deer Park mine at Rossland.

A. W. MCCUNE of Salt Lake, Utah, is reported having sold his interest in the Payne mine at Rossland, B. C., for $900,000.

E. H. WEBSTER, secretary at Minas Prietas, Mexico, Grand Central M. Co., Supt. during E. Abadie's absence, will resign March 31st.

J. P. STIDGER of Brown's Valley, Cal., has been engaged by a syndicate to go to Dawson, Alaska, to take charge of mining interests near there.

GEO. MOORE, metallurgist for the Con. Kansas City Smelting & Refining Co., has been making an examination of the mines of Tuscarora, Nev.

W. T. HARPER, Pres. University of Chicago, will deliver the public address at the California University charter day celebration, March 23d, at Berkeley.

A. B. ADAMS has returned to San Francisco from Mexico and reports forming the Consolidated Mines of Copalquin in Durango. He wants bids on an electric machinery plant to be erected at the junction of the Limon and Copalquin rivers.

FROM San Francisco Richard Johnson writes the Nogales, Ariz., *Oasis* that he has sold the Cobato mine, in the Altar district, Sonora, Mexico, for "$100,000 in gold."

GEO. O. WALKER, formerly Supt. Sacramento mine, at Mercur, Utah, has accepted the superintendency of the properties of the Idaho Con. M. Co., in the Buffalo Hump district, Idaho.

P. E. DEVILLE, who claims to have been the original discoverer and locator of the Treadwell mine, Douglass island, Alaska, is back from the Klondike, where he is credited with having become a millionaire.

PROF. WILLIAM P. BLACK, Territorial Geologist of Arizona, is working on an elaborate report of that Territory's resources, which, it is said, will be tendered the Legislature without charge.

E. R. KRAUSE has been appointed ancillary receiver for Boston & Montana Con. C. & S. M. Co. at Silver Bow Co., Mont., in a suit brought by James Forrester and John McGinnis, stockholders, for a dissolution of the corporation. Thomas B. Hinds had been appointed receiver for the company last December.

ACCORDING to a Seattle paper, Henry Bratnober, who is now in London, has decided to open offices there and at Skagway for himself, as a mining promoter, and to leave the service of the London Exploration Co. In this he follows the example of his predecessor, Hamilton Smith, whom he succeeded as chief agent of the London Exploration Co. in this part of the world.

T. H. EVANS, who is announced in Boston as having "introduced the cyanide system of gold concentration into South Africa," is visiting New York from Mexico, where he has been gathering copper specimens. They run "from 3% to 8% in metal, and their richness so impressed Mr. Evans that he carefully preserved them and brought them to New York."

"JIM" WARDNER is again heard from. This time he says he has a silver-lead mine near St. Michaels, Alaska, twenty miles from tidewater, that "runs 75 to 125 ounces silver and 60% lead;" that he has raised money to build twenty miles of railroad to get the ore to the beach for ship transportation to the smelter, and has contracted to so ship 500,000 tons of this silver-lead ore. The customary shipwrecked sailors near Golovan bay discovered the aforesaid mine some years ago, and it is now a great thing.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey, Strong & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING FEBRUARY 28, 1899.

620,267.—PISTON ROD GUIDE—F. M. Anable, Westville, Cal.
620,417.—VOTING MACHINE—J. E. Chapin, North Fork, Cal.
620,419.—NAME PLATE—Clark & Wattson, S. F.
620,285.—REVOLVING PLOW—M. C. Dethiefs, Willows, Cal.
620,290.—SUPERHEATING APPARATUS—P. F. Dundon, S. F.
620,292.—FLY TRAP—M. S. Featherstone, Goshen, Cal.
620,436.—PERFORATING MACHINE—J. J. Flett, Corvallis, Or.
620,438.—CABLE GRIP—G. S. Fouts, S. F.
620,119.—CAR VENTILATOR—Graham & Pierce, Sacramento, Cal.
620,546.—CULTIVATOR—G. G. Guenther, Orange, Cal.
620,244.—SNOW SHEDS—C. F. McGlashan, Truckee, Cal.
620,345.—FOLDING STOVE—J. Morawetz, Castella, Cal.
620,346.—EXERCISING DEVICE—A. C. Mueller, Oakland, Cal.
620,169.—TRANSMITTING POWER—H. Paulson, Sumner, Cal.
620,174.—CAR VENTILATOR—E. R. M. Pierce, Sacramento, Cal.
620,250.—CUP POLISHING APPARATUS—O. F. Pira, Oakland, Cal.
620,552.—WASHING MACHINE—J. H. Therien, S. F.
620,262.—CAN FAUCET—G. F. Tong, Sacramento, Cal.
620,381.—LINOTYPE MACHINE—Trounsell & Trego, S. F.
620,264.—MINING APPARATUS—S. W. Wible, Bakersfield, Cal.
30,274.—DESIGN, HORSE PAD—E. D. Flint, Oakland, Cal.

NOTE.—Plain and Certified Copies of U. S. and Foreign patents obtained by Dewey, Strong & Co., by mail or telegraphic order. American and Foreign patents secured, and general patent business transacted with perfect security, at reasonable rates, and in the shortest possible time.

Recent Mining Incorporations.

South Sliger G. M. Co., San Francisco; capital stock $150,000, subscribed $50; A F. Baumgartner, J. L. Daniels, E. B. Cushman, W. H. Metson, C. W. Keeney.

Hanford Mica M. Co., Hanford, Cal.; capital stock $80,000; subscribed $60,000; P. McRae, K. H. Sim, R. Irwin, T. S. Esrey, N. P. Duncan, D. Finn, L. Nathan.

Green Jumper G. M. & D. Co., Sonora, Cal.; capital stock, $52,500; subscribed, $50,000; J. T. Ryan, E. J. Landers, F. Corbin, J. W. Purdy, W. S. Risley.

Amarillas G. M. Co., San Francisco; capital stock, $100,060; subscribed, $25; E. A. Abbott, M J. Kast, W. J. Wilson, W. E. Tucker, W. W. Kaye.

Obituary.

J. M. BRYAN, the patentee of the Bryan mill, died at Smith's Flat, El Dorado Co., Cal., last Monday, aged sixty years.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

ADJUSTABLE GUIDE FOR ROCK DRILL PISTON RODS.—Francis M. Anable, Westville, Cal. No. 620,267. Dated Feb. 28, 1899. This invention relates to an improvement in rock drills. It consists essentially of supplemental removable segmental linings fitting in correspondingly-shaped sunken chambers, which are formed in the heads through which the piston rod passes, and means for adjustably securing these lining sections therein, so they may at any time be set up and adjusted, to compensate for the wear caused by the weight and friction of the parts, and to keep the piston rod in constant alignment.

HORSE SHOE PAD.—E. D. Flint, Oakland, Cal. No. 30,274. Dated Feb. 28, 1899. This invention comprises a novel design for an elastic pad which is adapted to be fitted to the foot of a horse and to have the iron portion of the shoe applied to the exterior so that the pad forms a cushion and protects the horse's foot from injury.

SNOW SHED CONSTRUCTION.—C. F. McGlashan, Truckee, Cal. No. 620,244. Dated Feb. 28, 1899. The object of this invention is to provide a means for preventing the excessive drifting of snow and consequent blockade of railway tracks in snowy and mountainous regions. It consists in the employment of wire screens, which, when applied to snow sheds and structures of like character, form a sufficient check to prevent the entrance of the snow, while at the same time they allow the light and air to enter and provide a free escape for the smoke and products of combustion, which so vitiate the atmosphere of these sheds when they are covered and surrounded by snow. The same arrangement of screens, when fixed to suitable framework, said framework being set up transversely to the drift of the snow, will afford a sufficient lodgment to prevent the drifts from forming upon the line of the track.

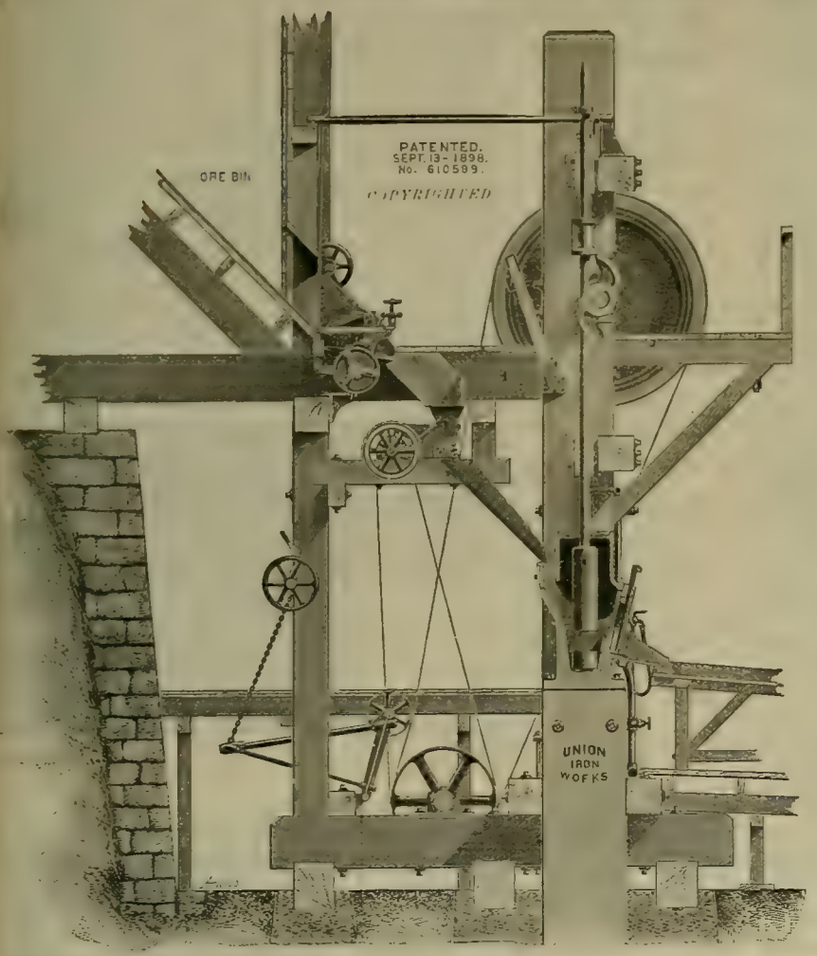
CUP POLISHING APPARATUS.—O. F. Pira, Oakland, Cal. No. 620,250. Dated Feb. 28, 1899. The object of this invention is specially to provide a means for the rapid cleaning and polishing of individual communion cups such as are now being employed in the communion service of churches, and generally for any rapid polishing of interior and exterior surfaces. It consists essentially of a horizontally journalled shaft having the opposite ends provided respectively with right and left screw-threads, tapering heads fitted upon the ends, one having a gradually increasing diameter from the outer to the inner end, and the other being hollow and correspondingly tapered. Both of these heads are provided with any fibrous cleansing substance and the shaft, when rotated, gives motion to the heads so that a cup to be polished may first have its exterior surface polished by introducing it into the hollow head, then it may be fitted over the opposite conical head to clean the interior, the work being done very rapidly by this means.

MINING APPARATUS.—S. W. Wible, Bakersfield, Cal. No. 620,264. Dated Feb. 28, 1899. The object of this invention is to combine in a single continuous apparatus devices for separating and saving gold from its intermixture with foreign substances, and in so combining the various devices as to economize labor and expedite the work by making all parts of it essentially continuous and automatic. The apparatus is more especially designed for use in river beds and low places where there is not sufficient natural fall to allow the work to be done. A sluice of any suitable construction having transverse riffles and pockets for mercury, brings the auriferous sand and material down to the point where an undercurrent is located, which takes out a portion of the fine material, leaving the coarser material to pass on to a point where it is transferred to what is known as a "siphon elevator." At this point such material as cannot be handled by the elevator is carried off by a grating over which it passes, leaving other material to fall through into the bottom of the sluice. The grating connects with delivery spouts which transfer to one side or other of the main sluice and thus dispose of the larger material. The jet of water is discharged in line with the open end of the elevator pipe and the material which falls through the grating is received upon a bottom in line between the water discharge nozzle and the elevator so that all material is carried in and thus elevated to any desired point. Supplemental jet pipes open into the elevator at different points so as to give an additional momentum. These jets are all supplied from a common distributer into which the water is brought under any suitable or obtainable head or pressure and is delivered therefrom to points where it is to be used with any relatively reduced pressure which can be controlled by gates. A momentum water wheel driven by one of the jets serves to operate the traveling portion of the machinery.

CAN FAUCET.—G. F. Tong, Sacramento, Cal., assignor to M. K. Barrett. No. 620,262. Dated Feb. 28, 1899. This invention is designed to provide a discharge faucet for closed cans, and in conjunction with it an ore supply device which allows air to enter the can as the liquid is withdrawn from it. The faucet is especially designed to be applied to the original five-gallon cans in which such products as coal oil, gasoline, etc., are placed on the market, and it is then only necessary to invert the can, set it upon a suitable support, leaving the faucet projecting to one side in readiness to draw therefrom. The arrangement of air passages is such as to prevent any supplemental drip after the cock has been closed, and it enables the user to withdraw the entire contents of the can without waste.

UNION IRON WORKS,

222 Market Street, San Francisco, Cal.



THIS ILLUSTRATION

Shows our patent Improved Stamp Mill, with Secondary Crusher, which increases the capacity of the ordinary stamp battery from 25 to 30 per cent.

We respectfully invite the attention of those contemplating the erection of new mills to this practical improvement.

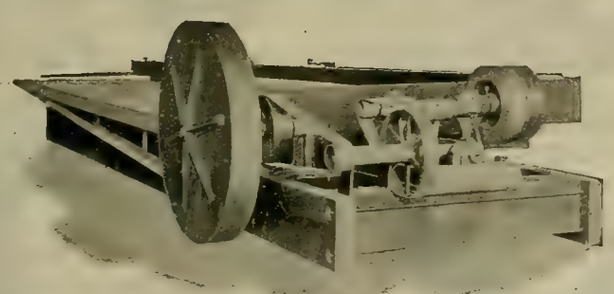
WILFLEY CONCENTRATOR.



The Wilfley Table is fully covered by U. S. patents Nos. 580,338 and 590,675. Infringements will be prosecuted to the full extent of the law.

PRICE, $450, F. O. B., San Francisco.

One of these machines will take the place of two or three belt concentrators of any style and do very much better work.

Some Practical Reasons Why the Wilfley Concentrator Should Be Used in Gold Mills:

1. It will successfully handle three or four times more material than any belt Concentrator made, without exception.
2. It will save more sulphurets in proportion while so doing, and catch any float gold, amalgam or quicksilver which may escape from mortars or plates.
3. It will make cleaner and much more valuable concentrates, thus saving useless expense for transporting valueless material, as also extra cost for treatment.
4. It requires little or no attention when once adjusted and no expert is required to either adjust or run the machine.
5. It will save much expense in power and room, and the first cost of a mill requiring concentrators.
6. It has no expensive belts to crack and wear out, nor complicated machinery to keep in repair.
7. It is the only sensible plan of concentration, as any kind of material can be worked, which is not true of any style of belt machine.

NOTICE TO CONTRACTORS.

NOTICE TO CONTRACTORS.—Sealed proposals will be received on or before one (1) o'clock P. M., April 12th, 1899, for the construction and completion of certain additions to the existing water works owned and controlled by the City of Seattle, Washington. The said additions include a gravity water supply from Cedar river, reservoirs and portions of an auxiliary high service system in the city. The contract will be let in four (4) separate subdivisions, and will embrace the following general terms of construction:

In Subdivision One (1):

Head works on Cedar river, consisting of Diverting Weir, Intake Canal (400 feet long), Settling Basin, Gate House, Dwelling House and Stable.

Pressure Pipe from Head works to High Service Reservoir in City Park, said pipe being 42 inches in diameter and 28.1 miles in length; of which 6.1 miles are to be riveted steel and 22 miles to be wooden stave pipe banded with steel bands ¾ inch in diameter, wooden stave and steel pipe between High and Low Service Reservoirs, 30 inches in diameter, about one mile in length.

Wooden Stave Pipe 24 and 30 inches in diameter respectively, about 4900 lineal feet, as waste pipe from High Service Reservoir to Lake Union. Change of Cedar River channel, 65,000 cubic yards excavation.

Improvements at Swan Lake, consisting of clearing land, construction of dam at outlet, Intake and pipe connection with said Lake.

In Subdivision Two (2):

High Service Reservoir and Gate House in City Park (capacity of said reservoir being about 16 million gallons); Low Service Reservoir with Gate House and Pumping Plant in Nagle Addition (capacity of reservoir about 20 millions gallons; capacity of pumping plant 3 millions gallons in 24 hours).

In Subdivision Three (3):

Stand Pipe on Queen Anne Hill, 30 feet diameter by 60 feet high, incased in "Ransome Concrete."

Force main from Low Service Reservoir to Stand Pipe on Queen Anne Hill, also to Renton Hill, said mains consisting of 13,200 lineal feet of 12-inch and 2690 lineal feet of 16-inch Kalamein pipe.

In Subdivision Four (4):

Pipe line from the Low Service Reservair to the present distributing system, consisting of 3580 lineal feet 30-inch riveted steel and 1240 lineal feet 30 inch cast iron pipe, also 250 lineal feet 24 inch riveted steel pipe, for connecting said reservoir with Tenth Avenue Sewer.

Separate bids will be received and separate contracts will be let for each of said subdivisions. The work will be let to the lowest bidders therefor. The total cost of said work is limited to $1,250,000. The contract to be entered into will provide that payment shall be made for this work only by warrants upon the "Cedar River Water Supply Fund of Seattle," as created and established by Ordinance No. 3990 as amended by Ordinance No. 5258, and the contractor shall have no claim against the city except as therein provided. Said ordinance provides that such warrants shall have interest coupons attached, and shall bear interest at the rate of five (5) per cent per annum, payable semi-annually on the first days of January and July of each year; and the city of Seattle absolutely and irrevocably pledges, out of the revenues from its water works system now owned, or which may hereafter be owned operated or controlled by it, a sum not less than one hundred thousand ($100,000) per annum, to pay the principal and interest of said warrants as aforesaid, when the same shall become due.

In addition to the warrants which will be issued in payment for the construction of said additions, the contractor will also be required to purchase at par any and all warrants which shall be drawn on said fund by the city in such amounts as shall be required to pay for any real estate, rights, easements or privileges necessary for the prosecution of the work of construction and the perpetual control by said city of the additions to the water works herein specified, whether obtained by purchase, agreement or condemnation proceedings, and also such warrants as shall be drawn upon said fund by the city in payment of engineering and other expenses necessarily incurred in connection with said additions; provided, that the total amount of the warrants thus required to be purchased by the contractor shall in no case exceed the sum of sixty thousand ($60,000) dollars, and shall be distributed as follows, to wit:

Against subdivision No. 1, the sum of forty-five thousand ($45,000) dollars; against subdivision No. 2, twelve thousand ($12,000) dollars; against subdivision No. 3, two thousand ($2,000) dollars; against subdivision No. 4, one thousand ($1,000) dollars.

Each bid must be accompanied by a certified check, payable to the order of the City Comptroller, for a sum not less than five (5) per cent of the amount of the bid, and no bid will be considered unless accompanied by such check.

The successful bidder will be required to enter into a contract and furnish satisfactory bond for the amount required by the City Charter and the laws of the State of Washington, within ten days after being notified of the award of the contract to him; failing so to do, the said check and the amount thereof shall be forfeited to the city. No person is eligible as a bidder who has within two years prior to the letting of said contract made default in payment of any just claim for any work or labor performed, or any skill or material furnished pursuant to any such contract as herein advertised, or who within said two years failed to complete any such contracts.

Special attention is called to article xxiii. of the City Charter, as now in force, relating to "hours of labor."

All bids must be made in accordance and compliance with the plans and specifications now on file in the office of the Secretary of the Board of Public Works, and in compliance with Ordinance No. 3990 as amended by Ordinance No. 5258.

The City of Seattle reserves the right to reject any and all bids.

Proposals must be endorsed on envelope "Bid for Constructing Subdivision No. —— of Certain Additions to the Water Works of the City of Seattle."

By order of the Board of Public Works.
FRANK OLESON, Secretary.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY, STRONG & CO., Patent Agents, 330 Market St., San Francisco, Cal.

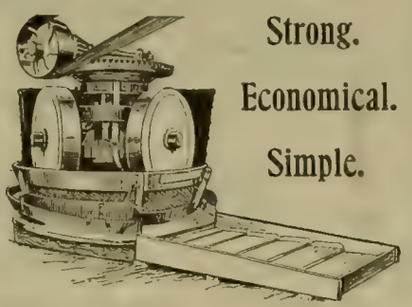
GEO. W. BARNHART, No. 4 Sutter St., San Francisco, Cal.

THE BRYAN ROLLER QUARTZ MILL.

We are the sole manufacturers of this Mill. A test made by the Bullion-Beck Co. of Eureka, Utah, with this and the Huntington Mill proved conclusively every claim we made for the Bryan Mill, viz: that the Bryan would crush more ore with less repairs, less power and less slimes than any Mill made. Result—they are now operating three of the five-foot Bryan Mills and find them superior and more satisfactory than any Mill they ever used. L. C. Trent & Co., who had formerly sold the Huntington Mill, immediately manufactured a Mill infringing our patent. Suit brought in the U. S. Court resulted in a verdict in our favor, and we shall prosecute to the full extent of the law any infringement of any character whatsoever in the MAKING, USING or SELLING of the same.



Strong.

Economical.

Simple.

MANUFACTURED BY

The BRYAN MILL is constructed on the principle of the Chili Mill, except it has three rollers arranged to run in a continuous discharging pan. It crushes either gold or silver ores. It consists of an annular cast-iron mortar with fixed steel dies arranged in the path of its three crushing rollers. Power is applied direct from a pulley through a bevel gear and pinion secured to stationary center post. We present a few of many advantages it possesses over any other Mill: Larger screen capacity and free discharge. Amalgamates a larger percentage of gold. Quickly and cheaply erected; with regular feed and proper flow of water requires little attention. Crushes hard or soft ore with smaller amount of power per ton and less wear and tear of machinery.

Send for Catalogue No. 8.

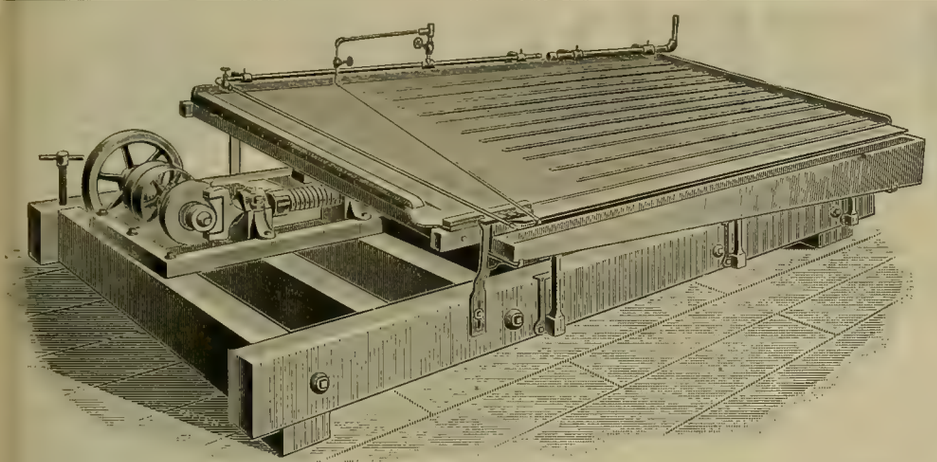
SAN FRANCISCO, CAL., U. S. A.



WOODBURY'S IMPERIAL CONCENTRATING TABLE.

THE Imperial Concentrating and Amalgamating Table is the latest invention of Mr. Geo. E. Woodbury, whose fame as one of the pioneer concentrator builders is world wide, machines of his manufacture being in general use in every country on the globe where the milling of ores is carried on. This Table is, however, built on entirely new lines, differing materially from either the well-known belt or bumping table types of concentrators.

SIMPLE IN ITS CONSTRUCTION.

SAVES FINE SULPHURETS.

WITHOUT LOS IN TAILINGS.

MAKES HIGH PRODUCT.

CAPACITY FROM 5 TO 10 STAMPS.

OFFICE OF WILDMAN GOLD MINING COMPANY. SUTTER CREEK, CAL., June 28, 1898.

Globe Iron Works, corner Main and Commerce Streets, Stockton, Cal.—GENTLEMEN: Replying to your inquiry about the Globe Patent Battery Stem Guides furnished us by you last fall, will say that you supplied us with Guides enough for ten stamps of the Wildman Mill. These Guides have been in constant use for the past eight months, and so far **do not show any wear either on the Guides or the Stems.** They are more convenient than any Guide I ever handled, and much time is saved with them in changing stems, etc. The Guide can be set so close you always get a fair blow on your dies, and the use of these Guides materially increases the crushing capacity of your batteries. **It is our intention to replace all of our Guides with those of your make,** and I cheerfully recommend them to any one desiring a good, serviceable and economical Guide. Very truly yours, JOHN ROSS, JR., Superintendent.

PATENTS

DEWEY, STRONG & CO'S PATENT AGENCY.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American reports, with full copies of U. S. Patents since 1872. All worthy inventions patented through DEWEY, STRONG & CO.'S Patent Agency will have the benefit of a description in the *Mining and Scientific Press*. We transact every branch of patent business, and obtain patents in all countries which grant protection to inventors. The large majority of U. S. and foreign patents issued to inventors on the Pacific Coast have been obtained through our agency. We can give the best and *most reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and circulars free.

Market Reports.

The Markets.

SAN FRANCISCO, March 9, 1899.

SILVER. — London, 27⅛d; New York, 59⅝; San Francisco, 59⅝; Mexican Dollars, 47⅛@48. New York exchange, sight, 15; telegraphic, 17½ cents premium.

LEAD.—New York reports "firm," $4.30@$4.35; brokers' price, $4.10.

Local, pipe, 7@7¼c; sheet, 7@8c; pig, 6¾c; bar, 7c.

COPPER.—New York reports Lake unchanged, $17.75; brokers' price, $18. Local, bar, 21¼c per lb.

England's imports of copper during January increased, as compared with '98, nearly 64% in quantity and 38% in value.

IRON.—American, soft, $22@24 per ton; Scotch, $27. Local bar, 2½c per lb. A Pittsburg dispatch says steel billets on the 8th sold at $24 a ton, the highest price since 1890. Several large sales were made at that price.

TIN.—Pig, 30c per lb.; Bar, 35c. New York reports firm, $24.

ANTIMONY.—16.

BABBITT METAL.—No. 3, 8c.

QUICKSILVER.—Local, $42.50; export, $39@39.50; carload lots, special rates.

Speaking of California quicksilver stocks, in Boston, where the stock is mostly owned and controlled, a paper says the New Indria, the newest of the quicksilver properties, out within the last two years at $5 per share, is at the present time producing 400 flasks of quicksilver per month, against a production of 600 flasks by the Napa, 300 flasks by the Ætna. The demand for quicksilver has cut down stocks on hand to between 5000 and 6000 flasks in this country, whereas a normal supply has been between 10,000 and 12,000 flasks, and a years ago a stock of between 25,000 and 30,000 flasks was not considered abnormal. The New Idria has a surplus of over $100,000 and is earning greatly in excess of the 80c per share it is now paying.

Ætna Quicksilver has been at 3¾ to 4 per share for many months, although paying 40c per share per annum dividend. It has now advanced to 4¼.

POWDER.—F. o. b., San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15¼c; less than one ton, 17¼c. No. 1* 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2* 35%, carload lots, 9¼c; less than one ton, 11¼c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

FUSE.—Triple tape, $5.10 per 1000 feet; double tape, $4.35; single tape, $3.45; Hemp, $3; Cement No. 2, $4.35; Cement No. 1, $3.45.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9.

San Francisco Stock Board Sales.

SAN FRANCISCO, March 9, 1899.

Pending pumping results matters move slowly in the local stock market. In other stock exchanges it is different. Denver, Colorado Springs and Salt Lake City report considerable activity. In the East there is a tremendous rush, especially in copper stocks which everybody wants:

It is the old story repeated for the hundreth time. The mass of men move only in droves, and until one or more courageous leaders show them the way they hesitate and hang back. After they once start, however, they keep going until they get a fright or are tired out and then they stop and perhaps retreat as fast as they advanced. If all the buyers of stock in times like these in the East were investors who paid cash for their purchases and stowed them away to keep, it would not be safe to predict a reaction from the upward movement that is now going on. Buying for the sake of income will not give way to a selling because of a failure of income, until such a failure actually occurs. From all appearances stock and bonds which now pay dividends and interest may be counted upon to continue to pay them for months if not years to come. With those on the other hand who have bought merely to sell again at a higher price than they have paid and especially those who have bought with borrowed money, the case is different. To such there very speedily comes a time when they get impatient of waiting for the expected profits and begin to be apprehensive that they may suffer a loss. As soon as this state of mind prevails the same energetic leadership which set in motion the rush to buy is able to start an equally general rush to sell. Whether or not things have reached this critical stage is therefore a question which every man must decide for himself as best he can and abide the result.

Commercial Paragraphs.

THE Warren Webster Co. of Trenton, N. J., is now represented in Denver, Colo., by Howard H. Fielding.

THE Denver office of Fairbanks, Morse & Co. reports the recent sale of five gasoline hoists, two gasoline air compressors, four steam engines for stamp mills, distributed through Colorado, Arizona, Utah and Idaho.

THE Pelton Water Wheel Co. have recently installed two wheels in the Ophir mine on the Comstock under such extraordinary conditions as to head as to be worthy of note. One of these is a 36-inch wheel direct connected to a fan used for ventilating the shafts, stopes and drifts of the mines. The other, a 32-inch wheel, direct connected to a dynamo used for lighting the mines. Both of these wheels are located at the Sutro Tunnel level, some 1700 feet below the surface, and run under a vertical head of 2020 feet. This is believed to be the highest head under which any water wheel has ever been operated, except a similar wheel furnished an adjoining mine some years ago, which runs under 2100 feet head. Some fifteen or twenty Pelton wheels are now running in the various Comstock mines under heads varying from 1200 to 2000 feet—operating dynamos, blowers, hoists, etc.

Catalogues Received.

THE third edition of Catalogue No. 17, "Gold Dredging Machinery," published by the Risdon Iron Works, is received. It is fully up to former catalogues of mining machinery published by that establishment, and contains the latest in the line of gold dredging machinery. The engravings are equal to those produced on the pages of a first-class magazine, and, with the accompanying descriptive matter, are printed on heavy calendered paper. The technical descriptions of the dredge are from practical articles from the London *Engineer*, the MINING AND SCIENTIFIC PRESS and other journals. This is the latest of a series of catalogues published by the Risdon Iron Works, Howard and Beale Sts., San Francisco. No. 3 is an 82-page pamphlet on "Hoisting Machinery," and is sent, postpaid, to any address on receipt of price—30 cents. No. 4 treats of "Tangential Water Wheels," 36 pp., 15 cents. No. 5, "Evans' Gravel Elevators," 48 pp., 15 cents. No. 6, "Hydraulic Machinery," 62 pp., 15 cents. No. 7, "Air Compressing Machinery," 96 pp., 30 cents. No. 8, "Bryan Roller Quartz Mill," 48 pp., 15 cents. No. 9, the same, in Spanish, 15 cents. No. 11, "Risdon Concentrators, 16 pp., 15 cents. No. 13, "Structural Iron Work," 60 pp., 15 cents. No. 14, "Johnson Concentrators," 16 pp., 15 cents. No. 17, "Gold Dredging Machinery," 48 pp., 15 cents. Bound copies, in cloth, 600 pp., $5 each.

Recently Declared Mining Dividends.

Swansea, Utah, $5000; March 10.

Empire State-Idaho M. & D. Co., 1½%; payable March 15.

Assessment Notices.

JUNCTION MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Tuolumne County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 4th day of February, 1899, an assessment (No. 23) of three (3) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, 106 Leidesdorff street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 13th day of March, 1899, will be delinquent and advertised for sale at public auction, and, unless payment is made before, will be sold on MONDAY, the 3rd day of April, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CALVERT MEADE, Secretary.

Office—106 Leidesdorff street, San Francisco, California.

ORLEANS MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Grass Valley, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 8th day of February, 1899, an assessment (No. 8, new series) of seven (7) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 324 Pine St., San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 14th day of March, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 5th day of April, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

GEO. P. THURSTON, Secretary.

Office—324 Pine St., San Francisco, California.

EUREKA CONSOLIDATED DRIFT MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Forest Hill Divide, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 9th day of March, 1899, an assessment (No. 17) of one-half of one cent per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 1209 Claus Spreckels building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 11th day of April, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 28th day of April, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

J. J. CRAWFORD, Secretary.

Office—1209 Claus Spreckels building, San Francisco, California.

BEST & BELCHER MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Virginia District, Storey County, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the seventh (7th) day of March, 1899, an assessment (No. 66) of ten (10c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, Room 33 Nevada Block, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the tenth (10th) day of April, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the second (2nd) day of May, 1899, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

M. JAFFE, Secretary.

Office—Room 33 Nevada Block, No. 309 Montgomery street, San Francisco, California.

DELINQUENT SALE NOTICE.

SILVER KING MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Pioneer Mining District, Pinal County, Arizona Territory.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 20) levied on the 10th day of January, 1899, the several amounts set opposite the names of the respective shareholders, as follows:

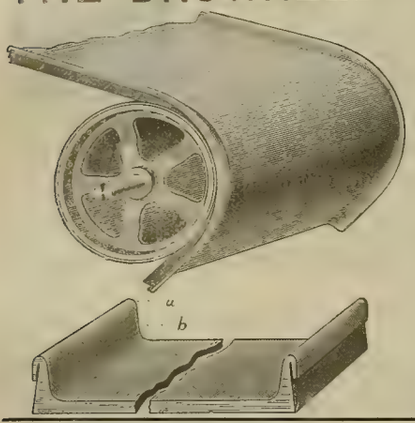
THE BROWNELL "PATENT LIP" FLANGE FRUE VANNER BELTS.



It has taken years of ceaseless testing and experimenting to produce the superior belt which we now offer, with elastic flanges and pliable body reinforced with specially woven duck. Every belt is manufactured by experienced workmen, and carefully tested on machines especially built for that purpose; consequently we are to-day manufacturing the best belts that mechanical ingenuity, combined with honesty of construction, can possibly produce.

SUPT. OFFICE WILDMAN GOLD MINING COMPANY, Sutter Creek, Amador Co., Cal., Feb 22, 1897.

MR. JAS. S. BROWNELL, 132 Market St., San Francisco, Cal.—DEAR SIR: Replying to your favor of the 18th inst., will say that in the two mills operated by this company we have nineteen of your Patent Lip flange concentrator belts in use; some of them have been in constant use for the past two years and have given entire satisfaction. I know of no better flange for a side shake machine.

Yours truly, JOHN ROSS JR., Superintdenent.

MEXICAN MILL. EMPIRE, NEV., March 28, 1897.

MR. J. S. BROWNELL, San Francisco, Cal.—DEAR SIR: For some years we have used three different styles of belts on our Frue vanner at the Mexican mill, and for smooth working and endurance the Brownell Patent Lip flange belt has proved its superiority over all others, and I unhesitatingly recommend it to all who are using Frue machines.

Yours truly, EUGENE MAY, Foreman.

For any information regarding Frue Vanner or Belts, call on or address

JAS. S. BROWNELL, Western Agent FRUE VANNING MACHINE CO.

(Successor to Adams & Carter.) 132 MARKET STREET, ROOM 15, SAN FRANCISCO.

RISDON IRON WORKS,

SAN FRANCISCO, CALIFORNIA.

Cable: "Risdon's." Code: A. B. C. & Leibers.

—MANUFACTURERS OF—

Gold Dredging Machinery

And COMPLETE EQUIPMENT for Placer Mines

OUR SPECIALTY.

We build **GOLD DREDGES COMPLETE IN RUNNING ORDER** to handle 2500 cubic yards per day at a cost of 3 cents per cubic yard. We excavate 50 feet below water, 20 feet above water and handle boulders up to one ton weight.

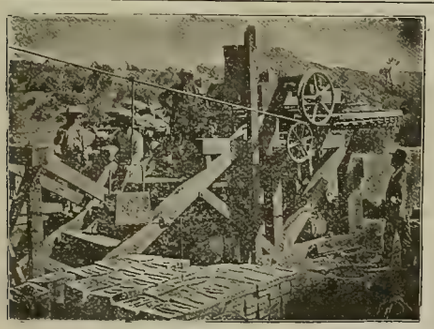
Send for Dredging Catalogues Nos. 15 and 16.

WE ALSO BUILD

All kinds of Mining, Milling, Concentrating, Pumping, Air Compressing, Hydraulic, Water Wheel and Hoisting Machinery.

EVANS HYDRAULIC GRAVEL ELEVATORS.

We publish sixteen catalogues. Write for one in the line you are interested in.



THE HALLIDIE ROPEWAY

For transporting Ore, Fuel, Merchandise, etc., in bulk or in packages. SIMPLE, ECONOMICAL, INEXPENSIVE, PRACTICAL.

LOADS MECHANICALLY. DUMPS AUTOMATICALLY. Send for Ropeway Pamphlet No. 20.

THE CALHOUN EXCAVATOR.

A COMBINED POWER-SHOVEL AND CABLEWAY.
.....Ask for Circular.....

Cableways, Double Rope Tramways, Wire Rope Transmissions, Incline Planes, Logging Machinery, Suspension Bridges,

DESIGNED, FURNISHED, ERECTED. Write for Estimates

CALIFORNIA WIRE WORKS, - 330 Market St., San Francisco, Cal.

THE BARTLETT CONCENTRATING TABLE.

One of these Machines will take the place of TWO or THREE Belt Concentrators of any make and do as good work.

Separates ALL the minerals from each other at one operation.

Gives THREE CONCENTRATES on the one Machine at the same operation.

The Machine is especially adapted to the separation of Zinc and Lead.

SIZE OF MACHINE.....4 ft. by 8 ft.

WEIGHT.....1000 lbs.

CAPACITY.....10 to 30 tons per 24 hrs.

CAN BE SET UP ANYWHERE.

REQUIRES NO SPECIAL FOUNDATION.

THREE CLASSES OF MACHINES ARE MADE.

Table A is adapted to concentration from 2 into 1 to 8 into 1.
Table B, 6 into 1 to 16 into 1.
Table C, 12 into 1 to 32 into 1.

Parties desiring tests made can send 500 lbs. or more, charges prepaid, and a run will be made and reports forwarded of the results, free of all charges, except for the assays, which will not exceed $10.00.

Price of the Table $300 Complete, f. o. b. Cars, San Francisco, Cal.

Licensee for the Manufacture and Sale, **PARKE & LACY CO.,** 21 & 23 FREMONT STREET, San Francisco, Cal.

—AGENT FOR—

KNOWLES PUMPS and PULSOMETER PUMPS,

INGERSOLL-SERGEANT ROCK DRILLS and AIR COMPRESSORS.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Ancient River Channels of the Forest Hill Divide, 285. Pitch Lake at Trinidad, 289. Latest Mining and Metallurgical Patents, 291. Lorden's Dry-Blowing Machine; Dry Blowers at Work, 292 Adjustable Automatic Weir at West Highlands, San Bernardino Co., Cal.; Large Weir with Double Gates Used in the Highland Irrigation District, 293. Furnace for Mine Ventilation, 294

EDITORIAL.—Activity in Copper Development; Change in the Hydraulic Ejector at the C. & C. Shaft; Stimulates Production of Zinc; Inquiries Concerning Chlorination Tailings; Conservatism Easily Overdone; Of Great Importance; Account of an Electric Light Plant at Johnson, Vermont; Fatalities from Powder Explosions; A California Mining Decision; A Notable Decision, 286.

MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 295-96-97.

THE MARKETS.—The Local Markets; Mining Share Market; Sales in San Francisco Stock Board, 310.

MISCELLANEOUS.—Concentrates, 287. A Decision of the Colorado Supreme Court, 288. The Genesis of Petroleum and Asphaltum in California. 289. Mysteries of the Ancient Rivers of the Forest Hill Divide, Placer Co., Cal.; Experiences of a Working Miner, 290. Latest Mining and Metallurgical Patents, 291. The Alluvial Deposits of Western Australia, 292. Automatic Division of Irrigation Water; Commercial Importance of a Pacific Cable, 293. Cheap Ventilation in Small Mines, 294. Industrial Notes; Commercial Paragraphs; The Lead Smelters' Combine; Personal, 297. List of U. S. Patents for Pacific Coast Inventors; Notices of Recent Patents; A Suggestion from Colorado; Catalogues Received: Books Received, 298. Recently Declared Mining Dividends, 310.

REGARDING the present activity in copper development consequent upon the great demand and appreciation in price, the remark of the Boston banker may continue to be quoted as it can not be improved, viz., that while copper is less easily sold at 18 cents, it is more easily produced.

A NEW YORK CITY technical journal gives an interesting account of an electric light plant at Johnson, Vermont, a village of 600 people. The total outlay was $5600. According to the New York paper's assertions, the village, which owns the plant, furnishes 16-candle power incandescent lights for $1 per year, and from that revenue is able to furnish free sixty public 30 candle power lights and show an annual net profit of 8% on the investment, which, like similar statements, is interesting if true.

IN mining operations conservatism is most important, but it can easily be overdone. All who know anything of mining are aware that a rich and well developed mine is as good an investment as can be found, but all realize with equal force that an absolutely undeveloped property has a great deal of the element of a gamble in it, and yet a prospect which makes a good showing on the surface justifies an amount of capital sufficient to test its worth; but because the surface prospect is good, the operator is not justified in ordering a plant of machinery having a capacity for a shaft half a mile deep, nor is a mill necessary until the quantity and character of the ore has been determined. The development of a prospect may be carried on in a satisfactory and economical way, and by pursuing this course mining is robbed of much of its risk.

EXCHANGES during the week past have brought the news of several fatalities resulting from powder explosions, one in Colorado resulting in the death of four men. In this case a large quantity of nitro powder exploded in a tunnel. The powder was no doubt kept in the mine to prevent freezing, but the practice of keeping large amounts of powder in the underground workings of a mine, where it is accessible to everyone, is a very bad one. Where climatic conditions are such as to require the powder to be kept underground there should be a separate place for it, in an abandoned drift or in an excavation made especially for it, and then accessible to but one man. Men should never be permitted to prepare their fuse, caps and powder near large quantities of powder, and caps particularly should be kept in a separate place. In another instance a Siskiyou Co., Cal., miner undertook to thaw nitro powder by placing it under his cabin stove, with the usual result—the destruction of his cabin, though he, being at a distance, was uninjured.

A Notable Decision.

In the issue of Feb. 18th appeared editorial reference to a decision just rendered by the Supreme Court of the State of Colorado. A brief recital of the facts was given. From the interest manifested it is deemed advisable to give the decision in full, which accordingly appears on page 288. Perusal of the opinion will give a clear understanding of the facts and of the line of argument that resulted in a reversal of the lower court, and a definite determination of the rule regarding the legal status of the locator of a lode claim on placer ground before patent for the placer is applied for, and also the extent of such lode claim.

The judges' decision is deemed worthy of place because of the information it contains, the recurrence everywhere of conditions similar to those constituting the point at issue, and the unusual absence of Supreme Court decisions on so important a matter.

The knowledge of the facts so clearly set forth on page 288 is of practical value to every owner or locator of a lode or placer claim, as such knowledge may save tedious and expensive delay and litigation in any similar contingency, if each party to such incipient controversy thoroughly understands his rights under the Federal statutes in such cases meant to apply.

It is clearly shown that the locators of the two lode claims had a right to these two claims, for they were "known to exist" at the time the owners of the placer claims in the same location applied for patent to the area embracing both lode and placer claims. In this part of the decision the Colorado Supreme Court decides against the Mt. Rosa possessors of the placer claims, and in favor of the holder of the lode claims within the limits of the Mt. Rosa placer holdings. But in the second part of the decision is the most important ruling, the court determining (for the first time, so far as known in a court of last resort) how much surface ground the successful lode locator in such placer ground is entitled to because of such admitted lode location. The lower court had allowed him the usual amount —600x1500 feet (300 feet each side of the vein, a distance of 1500 linear feet). When appealed, the Mt. Rosa Co. claimed that even if the lode locator in their placer ground were allowed to hold ground therein he was entitled only to a small portion of the usual 600x1500 feet, such portion to be determined by the Supreme Court. On this point the Appellate Court held that the placer claim took precedence; that it had the "right of way," so to speak, and that the lode claimant in such cases as the one under discussion should be allowed only just what would be absolutely required for convenient working of the lode, in this case 25 feet on each side of the strike of the vein, or 50x1500 feet, instead of 600x1500. In making this rule Justice Goddard evidently noted the express implication in Section 2333 of the United States Statutes and the precedent established by Judge Riner in the United States Circuit Court, who, in a similar case, determined that 25 feet each side of the vein was the minimum amount that a lode locator could get along with, and the maximum amount that he should receive when the rights of the placer locator were taken into account.

TOO MUCH importance cannot be attached to the advantage obtaining from carrying the development of mines far ahead of stoping operations. A mine that has no ground blocked out beyond its actual stopes is at best a hand-to-mouth affair. How much more satisfactory it is to have two or three levels opened and raises through and a large quantity of ore actually blocked out for stoping at any time. In some mines where this desirable state of affairs has been reached, it is not uncommon to see additional stamps set up to more speedily get rid of these reserves. This may be good business judgment, too, if the development is still continued in a vigorous manner. This is legitimate mining, and it is to be regretted that the policy is not more generally appreciated.

A California Mining Decision.

An important decision has been rendered by Judge Nicol of the Superior Court of Tuolumne county, Cal., in the case of the Argonaut Mining Co. vs. the Kennedy Mining Co. of Jackson, Amador county, Cal. The Argonaut Co. alleges in its complaint that the Kennedy Mining Co. has trespassed upon the property of plaintiff and extracted therefrom large amounts of valuable gold-bearing quartz. After elaborate preparations by both parties to the suit, a statement of facts was agreed upon by the attorneys for the contestants, which was submitted to the court September 15th, '98, at San Andreas, Cal. The case was subsequently argued in San Francisco. The litigation involves the apex and end line questions, and affects the extralateral rights of contestants. The Kennedy Co., prior to May 10th, '72, made application for a patent to its quartz claim, which was adversed by the Pioneer Mining Co., now the Argonaut Mining Co. A U. S. Deputy Surveyor was directed to make a survey and establish an end line dividing the Kennedy and Argonaut mines. This became known as the compromise line, and a patent was issued to the Kennedy Co. with reference to this line. In the meantime the Pioneer Co. made application for a patent, which was also subsequently granted. Both patents were issued subsequent to May 10th, '72. The Pioneer, or Argonaut claim, is bounded on the south by an agricultural patent issued prior to the application of the Pioneer Co. for a patent, and its south boundary line is consequently defined by this agricultural patent and is a due east and west line. The strike of the quartz vein through the Argonaut claim is about 20° west of north, and its north end line is approximately at a right angle with the strike of the vein, hence the end lines of the Argonaut mine are not parallel, but the claim was taken up and entered for patent under the laws of 1866, which did not require the end lines to be parallel. The Kennedy Co. contended that the end lines of the Argonaut claim should be parallel and assumed that the triangular section of ground which would lie between the eastward projection of the north end line of the Argonaut claim, and a line similarly projected drawn parallel with its south end line passing through the lode at its intersection with the Kennedy south end line, would become the property of the Kennedy Mining Co., and it is largely within this triangular section that the alleged trespass has been made. The court has decided in favor of plaintiff, establishing the end line as claimed by the Argonaut Co., and awarding judgment against the Kennedy Co. for $64,000—the net amount extracted by that company within the Argonaut extralateral right.

SINCE this paper published the statement that there were in California large quantities of chlorination tailings containing values of $5 per ton and upwards a number of letters have been received making inquiry concerning them. The experience of those who have tried experiments on material of this class would form a valuable contribution to the treatment of gold ores and the MINING AND SCIENTIFIC PRESS would like to hear from any who have conducted such experiments, whether by rechloridizing, cyaniding, amalgamation or otherwise.

A CHANGE has been made in the hydraulic ejector at the C. & C. shaft, Comstock mine, Virginia City, Nev. In the new arrangement the injecting water jets are introduced in the bottom of the elevator, in place of the sides, as in the first ejector. This permits a direct upward lift, with consequent suction, and is designed to obviate the vibratory motion in the lower part of the discharge column. The new castings in which this change has been introduced have not yet been placed in position.

PRESENT high price of copper stimulates production and retards industries wherein copper is a large factor. As in the case of copper, so with zinc. New localities are being scoured by prospectors and old ones are coming to the front with discoveries of ore, the existence of which, it would seem, had not been suspected. Out of the thousands of new locations are likely to come a few good mines. With the coming of spring the efforts of prospectors will be increased.

Concentrates.

REDDING, Cal., is one of the few places where miners are locally reported to be in demand.

"THE largest tin mine in the world" is believed to be that on the island of Sulo Brani, in the bay of Singapore, producing monthly over 1000 tons of tin.

PROF. FALK of Vienna announces the destruction of the world will take place on Nov. 13th, '99. Very well. Most of us can get along just as well without it.

THE proposed purchase of gold properties on Cedros island, off the Lower California coast, by W. A. Clark of Montana, has, as usual, awakened dormant claims thereto.

WITH lead at $2 60 in '97, the Gem, Idaho, mine like others of its class closed down. Better prices and prospects now occasion the unwatering and reworking of that property with new machinery.

No U. S. internal revenue stamps are required on preliminary filing or final mining location notices. Where title is transferred, stamps are required, the same as any other conveyance of real estate.

AMONG other unique forms of gold "mining" will appear this season a force of miners working in diving suits in the Sacramento river, Cal., between Redding and Keswick, superintended by M. Warren.

THE Denver, Colo., Mining Stock Exchange is about to attempt getting back at least a portion of the business enjoyed by Colorado Springs, Colo., mining brokers, lost by the former organization several years ago.

ON a claim located in July, '98, no matter how much work was put on it in that year, there must be $100 work or improvements put on the claim some time in '99 to enable the locator to legally hold it after Dec. 31st, '99.

A PATENT for an improvement on a machine does not restrict the use of the machine in its usual form. In the claim for an improvement the claim must be limited to the addition. It is void if it comprises the whole machine.

DIAMOND mining in Brazil is now carried on by small associations or by single individuals, in a cursory sort of way. At one time it was the most important diamond field in the world, and the quality of the stones is unsurpassed.

LATEST monthly report from the Alaska-Mexican mine shows the milling of 13,905 tons ore, yielding $1.85 per ton. During the month 275 tons sulphurets were saved, which are expected to smelt $30 per ton. The month's expenses were $23,062.

THE region around Johannesburg, South Africa, has produced gold to the amount of $900,000,000; California has produced gold to the amount of $1,310,000,000. In the former region there are now 5325 stamps in operation, crushing about 750,000 tons ore per month.

ANSWERING Trinity Center, Cal., Bisbee, Ariz., and Brigham, Utah, there is no federal law stating how much per day shall be reckoned as the base for annual assessment work on unpatented mining claims. The ruling rate of wages paid determines that matter in every locality.

THE three bills recently passed by the Oregon Legislature affecting the mining industry puts placer and quartz claims upon the same basis as real estate, provides for lien against mining claims for labor and supplies and for the appropriation of water for mining and power purposes.

THE price of copper may be made prohibitory. In one New England factory formerly consuming, it is said, 300 tons of copper per month, aluminum has been introduced to take the place of copper, and in another Babbitt metal is said to have been substituted for copper since the price of the red metal passed 14c.

A $20 GOLD PIECE weighs 516 grains and contains 464.4 grains fine gold. There is $20 worth of "pure gold" in a $20 gold piece; the 51.6 grains of alloy therein is to give the coin hardness and durability. Whether in the shape of a coin or a "melted nugget," the $20 gold piece, as it comes from the U. S. mint, is worth exactly $20 in gold.

THE present high price of zinc should stimulate prospecting in the Santa Ana mountains, in the Trabuco canyon, Orange Co., Cal., and that vicinity, for ores of that class. A large amount of development work has been done to develop lead-silver ore, but the ore contains more zinc than lead, and, having a silicious gangue, should concentrate readily.

SO FAR as learned, the underwriters of the American Smelting & Refining Co., the new smelter combine, are H. H. Rogers of the Standard Oil Co., Lewisohn Bros. and Moore & Schley. Of the $65,000,000 capitalization, one-half will be in preferred and one-half in common stock. The full details, as furnished by the parties themselves, appear on page 297.

EVERYTHING in the way of material that goes into the construction of mining machinery shows a general advance in price. Iron and steel especially show sharp rise in prices. So far there has been no advance in prices of manufactured articles, though it is manifest in the face of increased cost in all that goes to make up the finished product, it must advance too.

LONG distance telephone messages from nearly every part of California have been joyfully ringing in the MINING AND SCIENTIFIC PRESS office since the morning of the 15th, telling of copious rains in the foothills and snow in the mountains, insuring a busy season for the California miners. The rain was badly needed and clears the local business atmosphere.

THE latest available Russian platinum statistics are for '97, when that country produced six tons, or 95% of the entire world's output. Detailed technical accounts of the industry have repeatedly appeared herein, the latest being an exhaustive article written by a European mining engineer for the MINING AND SCIENTIFIC PRESS, and which appeared in the issues of Sept. 10th and 17th, '98.

TO FIND the area of a required pipe, the volume and velocity of water being given, multiply the number of cubic feet of water by 144, and divide the product by the velocity of the water in feet. The area being found, it is easy to get the diameter of pipe necessary. The area of a steam piston multiplied by the steam pressure gives the total amount of pressure exerted. The area of the water piston multiplied by the pressure of water per square inch gives the resistance. A margin must be made between the power and resistance to move the piston at the required speed, usually reckoned at about 50%.

THE company that is credited with intention to exploit the gravel deposit near Columbia, Tuolumne Co., Cal., by driving a 5000-foot tunnel from the Stanislaus river, is mainly composed of San Francisco men. The original incorporated name was the Columbia Tunnel & Exploration Co. The new company that is about to undertake the development will issue 1,000,000 shares of stock.

COPPER sulphide ore has been found in Aliso canyon near Acton, fifty-five miles northeast of Los Angeles, Cal., on the S. P. Railway. Near the summit of the San Gabriel mountains, on Wilson's peak, back of Pasadena, a vein has been opened in which is found considerable copper sulphide. At several localities in the San Gabriel canyon, above Azusa, copper ores are found, some of which are rich in gold and silver.

WITHIN thirty days from announcement, an appeal may be made from the decision of any local register and receiver to the Commissioner of the General Land Office. It must be printed or written, and must be brief and to the point. It must be forwarded through the local land office. Upon questions relating to private land claims, or disposal of public lands, an appeal may be taken from the ruling of the Commissioner of the General Land Office to the Secretary of the Interior.

IN '63 camels were brought from Asia Minor to the State of Nevada and there used to carry salt from Churchill and Esmeralda counties to the Washoe silver mills. They were thus used for several years. After the completion of the C. P. R. R. they served to carry wood from the Carson river. In '75 the Nevada Legislature prohibited their further appearance on highways, and the remnant of the herd was taken to Arizona, where it carried military supplies till the completion of the first railroad through that Territory.

A GOOD leather belt will resist a continuous strain of 350 pounds per square inch of section. Long belts are more effective than short ones for transmitting power. A belt will transmit 30% more power with the same tension when the grain (smooth) side is turned toward the pulley than when the flesh side is turned in. Belts draw better on smooth pulleys than on rough ones, and is about 50% greater on a leather-covered pulley than on a polished iron one. Belts should not be permitted to become hard and dry. This may be prevented by the occasional use of tallow or neats foot oil.

THE town of Eveleth, on the Minnesota iron range, is to have a novel experience. It will be moved bodily next month to a new site some distance from its present location, which has been found to be directly over a big bed of iron ore. The mining company that platted the present townsite reserved the mineral rights, so the townspeople have no alternative; and as the mining company has agreed to grade streets, lay sidewalks and move all the buildings at its own expense, there is no opposition, and the unique experience seems to be viewed as rather diverting than vexatious. The mining company has taken the precaution this time of satisfying itself, by diamond drilling and other tests, that there are no considerable iron deposits under the new townsite, as it doesn't care to stand the expense of a second transplanting of the whole town.

A GOOD cement for cast iron may be made of two ounces of sal-ammoniac, one ounce sulphur and sixteen ounces of cast-iron filings, these to be well mixed and kept dry. When required for use take of this mixture one part and of clear iron filings twenty parts; mix thoroughly in a mortar and make into a stiff paste with a little water. A little fine grindstone grit improves it. For face joints equal parts of red and white lead mixed with linseed oil forms a good cement. For joints in steam pipes take litharge in fine powder, two parts, very fine sand and quicklime (which has been allowed to slack slowly in a damp place), each one part. Mix and keep in air-tight can. When required make into a paste with boiled linseed oil. A good cement to secure tools in their handles is made of black resin four parts, beeswax one part, finely powdered brickdust one part.

AN interesting comparison of the insulating action of various materials has been instituted by Prof. Carpenter. If the loss of heat of a non-inclosed pipe is taken at 1, the following rotation of figures is obtained for the effect of the insulating agents: Pale gray lead paint coat, 1.267; two layers of asbestos paper, 0.777; one layer of asbestos board, 0.594; four layers of asbestos board, 0.503; a wooden pipe, 0.330; magnesia applied as paste, 0.224; slag wool, felt, 0.209; asbestos mixed with felt, 0.208; slag wool, fibrous, 0.203; asbestos with sponge, 0.180; two layers of asbestos paper, 2.5 millimeters felt, 0.170. The escape of heat seems to be increased by lead paints. Remarkable is the slight increase in the imperviousness in using four layers of asbestos board, as compared with the results obtained by the use of only one layer. Such results are of practical interest to manufacturers or users of devices in which heat must be, so far as possible, bottled up.

AT a recent meeting of the Chemical and Metallurgical Society of South Africa, the secretary read the following letter from M. T. Dixson: "In the interests of the gold industry in general and the cyanide process in particular, I would make public the great advantage of using glass as a flux for cyanide slimes, either in ordinary plumbago crucibles or—by preference—in clay liner crucibles. I think we here may lay claim to having been the first to adopt, after numerous experiments, on a large scale the use of glass as a primary flux. The proportions are for 100 pounds roasted slime (not acid treated), 50 pounds ground white glass and 50 pounds ordinary borax. This mixture in a clay liner pot will give gold 860 fine if treated in a fairly quick furnace. Slimes yielded treated 5.9 ounces troy gold per pound avoirdupois slimes. Perhaps the chief feature, after the refining, is the economy in its use, which should recommend its adoption generally."

A GALLON of water, "United States Standard," weighs 8⅓ pounds and contains 231 cubic inches. A cubic foot of water weighs 62½ pounds and contains 7½ gallons. Each nominal horse power of boilers requires 1 cubic foot of water per hour. In calculating horse power of steam boilers, consider for tubular or flue boilers 15 square feet of heating surface equal to 1 H. P. Condensing engines require from 20 to 25 gallons of water to condense the steam evaporated from 1 gallon of water. To find the pressure in pounds per square inch of a column of water, multiply the height of the column in feet by .434. Approximately, every foot of elevation is equal to a pressure of one-half pound per square inch. To find the height of a column of water in feet that will cause a given pressure in pounds per square inch, multiply the required pressure by 2.304. To find the velocity in feet per minute necessary to discharge a given volume of water in a given time, multiply the number of cubic feet of water by 144, and divide the product by the area of pipe in inches.

"YOUR paper is a necessity; I am lost without it," writes a mine superintendent from Santa Rosalia, Sonora, Mexico, just returned from the interior. "I would gladly send $10 a year for the MINING AND SCIENTIFIC PRESS were that the charge," says a Rossland, B. C., milliman. "It seems as if the MINING AND SCIENTIFIC PRESS always knew just what mining men wanted before anyone else has given it voice," writes a Colorado Springs mine officer. The Iquiqui, Chile, subscriber who was paid to 1903 is now exceeded by a Colorado subscriber, who is paid up to 1905. Commendations and flattering testimonials of merit are always appreciated, the constant effort being to deserve such kindly criticisms; yet, the paper always welcomes adverse criticism, and recognizes the value of friendly reference to any sin of omission or commission at any time. Everybody knows more than anybody, and any one of the thousands who everywhere in the mining world weekly see these pages, is cordially invited at any time to proffer criticism, suggestion or advice in the interest of all.

IN Cassel's method of chlorination by electrolysis chlorine is produced by the electrolysis of a solution of common salt, caustic lime being added to neutralize the hydrochloric acid produced by secondary reaction. The same apparatus serves for the generation of the chlorine, the chlorination or conversion of the gold into chloride and the precipitation of metallic gold. It consists of a large barrel, revolved on a hollow horizontal axis, which serves as the cathode for the collection of the gold as precipitated. The anodes are plates of retort carbon. The usual manhole is in the barrel for charging and discharging. The axle is covered with a filter of asbestos cloth; inside is an archimedean screw, working in packed boxes, to remove the gold as formed and carry it to the boxes at either end, exteriorly, to the barrels. The charge is about two tons of roasted ore, and sufficient solution of salt to make the pulp fluid, together with the necessary amount of quicklime. The barrel is given eight or ten revolutions per minute, and the current from the dynamo is turned on.

ELECTROLYTICAL copper refining in most large establishments is conducted in two ways—first, by means of a copper sulphate solution. Anodes are made from copper plates, carefully freed from antimony, arsenic and bismuth. The cathodes are formed by coating sheets of rolled copper with graphite, the depositing tanks are of wood, lined with thick sheetlead. When the current is switched on the solution decomposes and pure copper is deposited in thin films on the cathodes. Any gold, silver, platinum, bismuth, tin, antimony, arsenic, lead, slag, etc., which went into solution with the copper, and some small quantities of metallic copper, are precipitated at the bottom of the vats in the form of a thin, slimy mud. The second process utilizes chloride solutions. This method is sometimes applied to raw ores. The ore, after being calcined, is finely pulverized by dry crushing and charged with the leaching solution in large, revolving wooden vats, and rotated for several hours. The cupric chloride is then reduced to cuprous chloride, and run into tanks formed of wood and containing carbon anodes, which are separated from the cathodes by diaphragms, and electrolyzed. The spent liquor is filtered, and contains a considerable quantity of cupric chloride and hydrochloric acid, which is used again for dissolving copper from the ore.

A COLORADO miner furnishes a tabular "method for calculating cost per ton for stoping ore," taking as a basis the thickness of the pay streak at the point considered. He figures that, where the ore streak is 4 inches thick, the cost of stoping per ton is $17.33; where 6 inches thick, $11.55 per ton; 8 inches, $8.67; 10 inches, $6 93; 12 inches, $5.78; 14 inches, $4.95. It would seem a difficult matter to prepare a table which would show the approximate cost of stoping which would have general application, for the reason that the rocks enclosing the vein may be hard or soft, or may be massive or have a slaty or quicksand structure, and many other conditions, always differing, may obtain which have an important bearing on the subject. A vein which breaks freely from the walls can be more cheaply mined than one of the same size which is "frozen." A soft granulated vein can be more cheaply extracted than one of the same size that is hard when the country rock in each case is the same. In the former case in small veins the miner removes the vein and then shoots down the wall, while in the latter the vein is usually stripped and shot or gadded down where the country rock has been removed. In this matter, as in almost all others connected with mining, generalizations are not possible. What may apply almost universally in one locality will not answer in another.

ABOUT 60% of wood may be converted into liquid. While the strongest hydraulic pressure would not squeeze one-half of 1% of moisture from dry wood, by putting the same material into an iron retort and converting it into charcoal by means of heat, the gases and smoke to the extent of fully 65% of the weight of the wood may be condensed into liquid pyroligneous acid, from which are obtained wood alcohol, acetate of lime and wood tars. A cord of wood weighing 4000 pounds produces about 2650 pounds of pyroligneous acid and 700 pounds of charcoal. The pyroligneous acid from one cord of wood produces nine gallons of 82% crude wood alcohol, 200 pounds of acetate of lime and about twenty-five gallons of tar, besides thirty-five bushels of charcoal. After the pyroligneous acid is neutralized with lime the wood alcohol is distilled off, the lime holding the active acid in solution. After the separation of the wood spirit the remaining liquid is boiled down in open pans to a sugar, which is dried and becomes the acetate of lime of commerce. Acetate of lime is used for making acetic acid. Fully three-fifths of all the wood alcohol and acetate of lime produced in the world are made in the United States. Wood alcohol is a substitute for grain alcohol for manufacturing and mechanical purposes at one-third the cost. It is used principally as a solvent in the making of shellac varnish, in making celluloid, photographic paper, etc., makes dye tints, is antiseptic and used for liniments, etc.

A Decision of the Colorado Supreme Court.

Following is the full text of the recent decision of the Supreme Court of the State of Colorado in a case that has attracted considerable interest. In response to numerous requests the MINING AND SCIENTIFIC PRESS has procured the official decision, as follows:

No. 3738.—The Mt. Rosa Mining, Milling and Land Co., appellant, vs. J. S. Palmer, appellee; appeal from the District Court of El Paso county. Mr. Justice Goddard delivered the opinion of the court.

This is an action instituted by the appellee, plaintiff below, against appellant, the Mt. Rosa Mining, Milling and Land Co., defendant below, to quiet his title to two lode mining claims situated within the exterior boundaries of a certain tract of land conveyed to appellant by a government patent, as placer mining ground.

Upon the trial it was admitted that the lode claims were formally and regularly located as provided by law, except as to the discovery of mineral therein; that affidavit in lieu of labor, for the years subsequent to their location, were properly filed by the owners; that by proper conveyances the plaintiff became, and was, the owner of whatever title had been acquired by virtue of such locations.

It was further agreed that the placer owned by the defendant was located some time prior to the location of the lode claims; that the application for a patent was not made until after their location; that the defendant, through proper conveyances, was the owner of the placer.

The only questions of fact that remained in dispute were whether or not a vein or lode was discovered and known to exist in the Handy Andy and Newman claims, within the boundaries of the Mt. Rosa placer, at the time appellant applied for patent for such placer, on August 18, 1892. The court, though sitting in the exercise of its equity jurisdiction, called a jury, to which it submitted these questions. Their answers were in the affirmative, and were adopted by the court as a part of its findings; and thereupon, and from a consideration of all the evidence introduced, the court found that the facts established were substantially these:

That the grantors of plaintiff, on March 18 and April 5, 1892, entered upon the land included within the exterior boundaries of the Mt. Rosa placer, and located respectively the Handy Andy and the Newman lode mining claims, upon discoveries of mineral-bearing rock in place, within the boundaries of said claims, and subsequently performed all acts necessary to complete a valid location of said claims; that by duly executed and recorded deeds of conveyance plaintiff became vested with all right, title and interest in and to the same; that on November 7, 1892, the Mt. Rosa Mining, Milling and Land Co. made application in the proper United States land office for a patent for the Mt. Rosa placer mining claim, and on April 24, 1893, the patent therefor was issued; and it thereby became, and is still, seized of all the right, title and interest to the tract of land described therein.

The court also found, as conclusions of law, that the Handy Andy and Newman lode mining claims, respectively, had been duly discovered, located and recorded, within the exterior boundaries of the tract of land described in the Mt. Rosa placer patent before the time of said application; that the ground described in said lode mining claims was excepted out of the land described in, and conveyed by, the placer patent; that the plaintiff was, at the time of the commencement of this action, and still is, entitled to the possession of the ground described therein, and entered judgment in favor of plaintiff for the possession of the ground in dispute, enjoining defendant from asserting any interest adverse thereto, and for costs. To reverse this judgment the company brings the case here on appeal.

Error is claimed upon the refusal of the court to give certain instructions asked for by appellant, defining what constitutes a lode or vein of mineral under the statute. We think this subject was properly covered by the instructions given, and that therein the court gave the accepted definition; and also stated the necessary conditions that would constitute it a known lode under Section 2333, Rev. Stat. U. S. The evidence not being preserved in the below exceptions, we must presume it was sufficient to sustain the answers of the jury and findings of the court, that lodes were discovered and known to exist within said respective locations prior to the application for patent. The counsel for appellant contended that, notwithstanding this, appellee cannot maintain this action, for two reasons:

First—Because appellant, having made a valid location of the ground as a placer claim, it was entitled to the exclusive possession thereof, and the entry of plaintiff's grantors thereon was wrongful, and no possessory right to the lodes was acquired thereby.

Second—That if, notwithstanding such wrongful entry, valid locations of the lodes were made, the title thereby acquired is not sufficient to support an action to quiet title.

It is undoubtedly true that when a locator perfects a valid location to a lode or placer mining claim he is entitled to the exclusive possession and enjoyment of the lands located for all purposes granted by the Act of Congress. In the case of a lode location the land located is segregated from the public mineral domain of the government, and the grant confers upon the locator exclusive right of possession and enjoyment of the surface, and any lode, the top or apex of which is within its surface boundaries (Section 2322, Rev. Stat. U. S.); and so long as he complies with the requirements of the Act he can protect his possession of the surface of his claim, as well as such lodes, from invasion by any subsequent lode or placer locator. (Manuel vs. Wulff, 152 U. S., 505; Armstrong vs. Lower, 6 Colo., 393; McFeters vs. Pierson, 15 Colo., 201; Seymour vs. Fisher, 16 Colo., 188; Belk vs. Meagher, 104 U. S., 279; Gwillim vs. Donellan, 115 U. S., 45.)

On the other hand, those provisions of the statute that give the locator of a placer the right to locate and patent all other forms of mineral deposit included within the surface boundaries of his claim expressly except therefrom veins of quartz or other rock in place known to exist within its limits. (Sections 2329 and 2333, Rev. Stat. U. S.) Such lodes, therefore, are not the subject of a placer grant, and a placer location does not operate to confer the title or possession thereof upon the placer claimant, or withdraw them from subsequent location by others. In other words, the placer location gives a qualified possession of the ground located; that is to say, it confers upon the owner the exclusive right of possession of the surface area for all purposes incident to the use and operation of the same as a placer mining claim, and all unknown lodes and veins, but does not give right of possession to known lodes or veins within these limits. The right to the possession of such lodes or veins can be acquired only by locating them as lode claims. (Lindley on Mines, Vol. 1, Sec. 413; Aurora Lode vs. Bulger Hill & Nugget Gulch Placer, 23 L. D., 95; Reynolds vs. Iron S. M. Co., 116 U. S., 687.)

It has been universally held that a patent for a placer claim does not convey title nor right of possession to the patentee to any lodes known to exist therein at the time of application; that if he desires to obtain such title and possession he must comply with the provisions of Section 2333, and patent them as lode claims. In Reynolds vs. Iron S. M. Co., supra, Justice Miller, who delivered the opinion of the court, speaking upon this subject, said:

"We are of opinion that Congress meant that lodes and veins known to exist when a patent was asked for should be excluded from the grant as much as if they were described in clear terms. It was not intended to remit the question of their title to be raised by some one who had or might get a better title, but to assert that no title passed by the patent in such case from the United States. It remains in the United States at the time of the issuing of the patent, and in such case it does not pass to the patentee. He takes his surface land and his placer mine, and such lodes or veins of mineral matter within it as were unknown, but to such as were known to exist he gets by that patent no right whatever."

Since a patent conveys to the locator no other or different rights than those acquired under the location, it inevitably follows from the doctrine thus announced that he has no possession, and acquires no right to any lodes known to exist within his claim by virtue of his placer appropriation. In Aurora Lode vs. Bulger Hill & Nugget Gulch Placer, supra, Secretary Smith, in discussing the rights acquired by the placer locator, said:

"Such a location, in and of itself, does not establish any right in the claimant under it to the superficial area within its boundaries except as a placer claim or mine. Of its own force it cannot operate to give title to or property rights in any veins or lodes within its boundaries. True, a placer mining claim becomes property *as such* by discovery and location the same as a vein or lode claim, but it cannot and does not in itself in any sense give title to or property rights in veins or lodes; nor can it, in my judgment, operate to preclude a subsequent lawful discovery and location of veins or lodes within its boundaries."

And Mr. Lindley, in his admirable work on mines, after an elaborate and thorough discussion of the question, deduces the following conclusions:

"1. A perfected placer location does not confer the right to the possession of veins, or lodes, which may be found to exist within the placer limits at any time prior to filing an application for a placer patent.

"2. Such lodes may be appropriated (*a*) by the placer claimant, or (*b*) by others, provided the appropriation is effected by peaceable methods and in good faith."

While we recognize to its full extent the rule that precludes the initiation of a right through a trespass upon the lawful possession of another, we think, under the established facts in this case, appellant is not in a position to invoke its protection. The lodes in question were known to exist prior to the application for patent; and appellant, not having taken the necessary steps to obtain possession of them, they were open to location by others at the time they were located by the grantors of appellee. In making locations no right of appellant was invaded, and their validity, therefore, is in no way affected by the fact that they were made within the surface boundaries of a prior placer location.

In support of the second proposition it is urged by counsel for appellant that the mere possessory title to mining claims is not sufficient to support the action provided for in Section 255 of the Code. This section enacts that:

"An action may be brought by any person in possession, by himself or his tenant, of real property, against any person who claims an estate therein adverse to him, for the purpose of determining such adverse claim, estate or interest."

The estate acquired by the locator of a mining claim is an interest in real property; and although the paramount title remains in the Government, the Congress have universally recognized such interest as a freehold, and in all controversies arising between the locator and other persons as to any right or claim thereto he is treated as the owner in fee. (Mercer M. Co. vs. Fremont, 7 Cal., 317; Hughes vs. Devlin, 23 Cal., 502; Merritt vs. Judd, 14 Cal., 60; Roseville Alta M. Co. vs. Ia. Gulch M. Co., 15 Colo., 29; Forbes vs. Gracey, 94 U. S., 762)

As was said in Hughes vs. Devlin, supra:

"Although the ultimate title in fee in our public mineral lands is vested in the United States, yet as between individuals all transactions and all rights, interests and estates in the mines are treated as being an estate in fee, and as a distinct and vested right of property in the claimant or claimants thereof, founded upon their possession or appropriation of the land containing the mine. They are treated, as between themselves and all persons but the United States, as the owners of the land and the mines therein."

Such being the character of the locator's title, it is obvious that the provisions of the Code are as applicable to mining claims as to any other real property; and his right to avail himself of the remedy therein provided is too clear to admit of dispute. (Dahl vs. Rannheim, 132 U. S., 260; Perego vs. Dodge, 163 U. S., 160; Noyes vs. Mantle, 127 U. S., 348; Gillis vs. Downey, 29 Cir. Ct. App., 286)

Another and more serious question is presented, and that is as to the amount of surface ground appellee is entitled to, if any, under and by virtue of his lode locations. The court below awarded him the full amount claimed, to wit, 300 by 1500 feet, in each of the claims. It is insisted by counsel for appellant that he is entitled to only the mineral lodes, and not to any of the surface of the placer ground.

This precise question has never, to our knowledge, been discussed or determined by a court of final resort. It has, however, been passed upon by the land department; but its rulings are not in favor. In the case of the Shonbar Lode, 1 L. D., 551, Id. 3 L. D., 388, Mr. Secretary Teller ruled that the lode claimant, having failed to adverse the placer application for patent, he was restricted to his lode and 25 feet of surface on each side thereof. Subsequently, and after the decision in the case of Noyes vs. Mantle, 127 U. S., 348, Assistant Secretary Chandler held, in the case of the Pike's Peak Lode, 10 L. D., 200, that the limitation of the width of the lode claim in Section 2333 was only applicable where the placer claimant sought to patent the lode, but had no application to a lode claim perfected by another; that in the latter case the lode claim in its full extent should be excepted from the placer patent. It does not appear from the statement of this case whether the lode claim was located prior to the placer or not; but we infer from the fact that the Secretary quoted from, and relied upon, the decision in the case of Noyes vs. Mantle, supra, as supporting this conclusion, that the lode claim was the prior location; while in the case of Aurora Lode vs. Bulger Hill & Nugget Gulch Placer, supra, Secretary Smith held that the lode location did not carry with it any more surface ground than was necessary for the use and enjoyment of the lode. But this conclusion seems to have been influenced largely, if not altogether controlled, by the peculiar conditions of that particular claim, and the fact that the placer claimant had obtained judgment in an adverse proceeding theretofore instituted against an application by the lode claimant for a patent.

The question was also involved in the case of Campbell vs. Iron S. M. Co. in the Circuit Court of the United States for this test, Judge Riner presiding. He entertained the fact, and instructed the jury to the effect, that a lode claimant, in case of a recovery, was entitled to no more than the vein or lode and 50 feet of ground, extending 1500 feet in length. We think this instruction correctly defines the amount of surface ground to which a lode located within the boundaries of a placer is entitled under the provisions of Section 2333. As was said in Reynolds vs. Iron S. M. Co., supra:

"(This section) made provision for three distinct classes of cases: 1. When the applicant for a placer patent is at the time in possession of a vein or lode included within the boundaries of his placer claim he shall state that fact, and on payment of the sum required for a vein claim and 25 feet on each side of

it, at $5 per acre, and $2.50 for the remainder of the placer claim, his patent shall cover both.

"2. It enacted that where no such vein or lode is known to exist at the time the patent is applied for, the patent for a placer claim shall carry all valuable mineral and other deposits which may be found within the boundaries thereof.

"3. But any case where the applicant for the placer is not in possession of such lode or vein within the boundaries of his claim, but such vein is *known to exist*, and it is not referred to or mentioned in the claim or patent, then the *application shall be construed as a conclusive declaration that the claimant of the placer mine has no right to the possession of the vein or lode claim.*"

We think it is manifest that the vein or lode referred to in the first and third provisions is the same thing, and that whatever a placer claimant would acquire by availing himself of the privilege accorded him by the first provision of the section is reserved by virtue of the third provision; in other words, that the same extent of surface ground that is incident to such lode or vein, if located and patented by the placer claimant, is reserved from the placer patent in case of his failure to claim and patent the same. If he elects to patent the lode he is required to take 25 feet on each side of the center of the vein and pay therefor at the rate of $5 per acre. This is a privilege accorded him which he may avail himself of or not, as he sees fit. If he elects to waive this privilege he may do so in one of two ways: either by expressly excepting the lode from his placer location and application for patent, or remain silent in regard to it. If silent, then by implication he declares that he makes no claim to such lode, and by such silence is bound to the same extent, and in the same manner, but no further than he would have been by an express declaration. By electing to make no claim to a known lode, or express declaration in regard to it, he must be understood as claiming, for placer purposes, the greatest possible area within the boundaries of his placer claim, and should be held to have relinquished only that which he might have taken, which is the lode, with the amount of surface ground provided. Why should there be any difference between rights of claimants of known lodes within the boundaries of a placer? We know of none. The object of excepting known lodes from placer locations was to prevent titles to such lodes being obtained under the guise of a placer, at the same time in order to protect claimants to each character of mineral locations to the greatest extent, and preserve to each that which was most valuable for particular purposes in connection with each class of claims. The lode, for convenient working, could not be limited to less than 25 feet on each side of the center of the vein; and the placer, which would be valueless without such surface rights, is permitted to take title to the remaining area accordingly. Those who controvert this view base their contention upon the provisions of Section 2320, which, it is said, governs the length and width of all lode claims, whether made within the boundaries of a placer claim or not. An Act on a particular subject must be construed as a whole. Section 2320 refers to the location of lodes not conflicting with any other class of mineral locations, while by Section 2333 special conditions with reference to conflicts between the two classes of mineral claims are specially provided for; and to that extent, construing the Act as a whole as a limitation or qualification of the provisions of Section 2320, it relates, as stated, to the width of lode claims generally, and regulates the width of lode claims when made upon lodes within the boundaries of a placer, whether such lodes are located by the owner of the placer or by strangers to that title. By this construction full force and effect are given to both of these sections, and the purpose of the statute is carried out. The Government receives for its mineral lands the price fixed for lodes and placers respectively, and the superior right to the surface area of the placer claimant, acquired by his prior location or patent, is protected. It is the conclusion of a majority of the court that the limitation of the width of the lode claim in Section 2333 is not only applicable to the placer claimant, but applies as well to others who locate a lode within the boundaries of his previously located placer.

Chief Justice Campbell declines to express an opinion upon this question because, in his judgment, the stipulation entered into by counsel eliminates it from the case.

It follows that the court below erred in adjudging to appellee surface ground in excess of 25 feet on each side of the lodes in question. For this reason judgment is reversed and the case remanded, with instructions to enter judgment in accordance with the facts we have expressed.

Reversed.

The Genesis of Petroleum and Asphaltum in California.

NUMBER VII.

Written for the MINING AND SCIENTIFIC PRESS by A. S. COOPER.

Red Shales in the Island of Trinidad.—The formation of the island of Trinidad consists of clay, loose sands, shales, limestones, calcareous sandstones, indurated clays, porcelanites of brilliant red colors, with pitch deposits and lignite here and there.

The only substances containing sufficient carbon and hydrogen for the formation of asphalt and likely to be inclosed in the strata are vegetable remains. They are particularly abundant at La Brea, where most of the asphaltic beds have been originally carbonaceous and lignitic shales. Mineral springs abound throughout the island. In a series of loose sands, clay and shale lies Pitch lake, seemingly occupying a depression in the strata. To the southward of the lake the shore is made up of bold cliffs, the strata of which consist of indurated clays. They also present thick veins of porcelain jasper. Strata of loosely coherent sandstone also abound, some of which are impregnated with bitumen. Rounded pebbles of pitch and porcelain jasper form a beach at the foot of the cliffs. A species of coke is occasionally observed along the shore with a porous structure and the prismatic form of the artificial product, but, of course, much denser on account of the large proportion of earth. Near the lake is a red yellowish substance, semi-baked, evidencing a considerable degree of heat which attended its formation. Part of the impurities in the Trinidad asphalt consist of comminuted red clays or shales with some sand.

PITCH LAKE AT TRINIDAD, W. I.—From an old print.

It is evidently not adventitious at the surface, but must have been thoroughly incorporated and brought up from the depths with the bitumen, judging from the constant amount, dissemination and character in all parts of the deposit. Water containing all the mineral ingredients of strong thermal water is found in the Trinidad asphalt. The presence of borates, iodides and so many forms of sulphur compounds and other characteristics show that the water must be of the same origin as that of many thermal springs. This water in all unaltered pitch shows that the formation of the pitch and water must have been simultaneous and cannot be considered adventitious.

It would be impossible for water in any adventitious way to become intimately mixed with the bitumen so as to form practically an emulsion. Near the center of the lake is a body of pitch softer, blacker and newer than that of the remainder of the lake. Gas constantly issues from the cracks in the bitumen. Those phenomena show that asphalt is being distilled at the present time. The porcelanite and red shales must have been formed by heat created in the starata themselves as these shales are burned uniformly, in no place showing a greater degree of heat than in another. They are probably formed in the same manner as similar rocks in California. The depression in which Pitch lake lies was probably made by the subsidence of the surface of the earth caused by the heat contracting the underlying shale. There was no focus to this heat, no central point. If there was, in the material next to the central point the evidences of heat would be great, gradually decreasing as you went from the focus; this is not shown. To illustrate, bricks of very different qualities are to be found in the same kiln, for as the fire is applied below in arches, the lower bricks in their immediate vicinity will be burnt to great hardness or perhaps vitrified, those in the middle will be well burned and those on the top will be too little burned. Even then the bricks the farthest from the fire would not have been burned to this extent if it were not for the numerous flues left between the bricks in the construction of the kiln. The intense heat of a furnace is confined by a foot wall of fire bricks. Three feet of lava will confine the heat of melted rock underneath. From the uniform burning of these shales the heat must have originated in the shales themselves. A good, clean red heat is required for the burning of brick: it is fair to suppose that this temperature is required to produce red shales.

Porcelanites and vesicular clinkers are scattered throughout these red shales; they are not centralized. No fumeroles connect these porcelanites with a central fire. Moisture was concerned, as is evidenced by their even burning. Moisture was the vehicle of heat, or the burning would not have been so uniform in its effect if disseminated by conduction or radiation. The parts of the shale burned to porcelain resemble earthenware and stoneware; to burn earthenware and stoneware a clean, white heat is required.

Arborescent forms of huge scale of these hydrothermal shales extend their ramifications throughout the earth in the vicinity of bituminous deposits. This form also goes to show that their burning was accomplished by chemical action, with the presence of moisture, and not from radiation or conduction from a focalized fire. Nearly all readily solvent substances and all volatile substances have been removed from these red shales, or where solvent substances now exist in them they are different from those that were in them at the time of their formation. The noticeable bright red colors of these shales could not have been produced by the oxidation of the iron in the shales by water alone; heat must have been present to produce them. This heat would be sufficient to distill any carbonaceous substance contained in them.

In the metamorphic rocks of the San Rafael range of mountains of Santa Barbara county it can be plainly seen that these porcelanized shales were converted to serpentine. All gradations from shale to serpentine can be found: shales reddened by heat, porcelaneous masses still retaining the structure of shales and porcelain partly converted to serpentine. There are no visible signs of metamorphic action now in operation where the serpentine is exposed to view, but in the Tertiary shales and sandstones to the west, especially in the hills lying north and south of the Los Alamos valley, this metamorphic action is going on at the present time.

These red shales lie above and precede greater metamorphism, such as is exhibited by serpentine and quartzite and probably metamorphic granite. This can be seen where erosion has been great enough to expose the contact between metamorphic rock and red and unaltered shales. When burnt, the cracks and seams in the shale are large, showing the extent to which they have contracted. Near the surface the red shales are vesicular and look as if they had faulted. These red shales are very much distorted and contorted; many of the contortions have a radius of but a few feet. No carbonaceous matter exists in these red shales. No bituminous

substances exist in these red shales unless they have entered subsequently to their burning. There is also an absence of sulphur. Carbonaceous and bituminous substances and sulphur are disseminated throughout the strata adjoining the red shales.

(To be Continued.)

Mysteries of the Ancient Rivers of the Forest Hill Divide, Placer Co., Cal.

Written for the MINING AND SCIENTIFIC PRESS.

The recent announcement of the discovery by Felix Chappellet Jr., on the Forest Hill divide, near Centerville, Cal., of what is presumed to be a continuation of the rich channel worked in former years in the Dix mine, adds another interesting chapter to the history of the divide. The discovery was made in the workings of the Eureka Con. Co., after years of diligent search, under constant heavy expense, and evinces what determined effort intelligently directed may accomplish in solving the mysteries of that system of ancient river channels which in prehistoric times cut their sinuous courses through the valley that has since become a mountain—the Forest Hill divide. Years ago two mines were worked in the vicinity of this recent find. They were known, one as the Dix mine, the other as the Greek claim. Both were rich, but several thousand feet of unexplored ground lay between, and it was for the purpose of developing this section that the Eureka Con. Co. was formed. A large tract of land was bought and operations began to find the channel in the body of the mountain under hundreds of feet of andesite breccia and volcanic mud. The tunnel was driven straight in, through bedrock, a distance of 3000 feet, having discovered nothing. Then an inclined raise was put in, at 2100 feet from the mouth of the tunnel, until it broke through the bedrock and entered lava. This was on the rim of a channel. The rim was followed a short distance and a winze sunk 6 feet to bedrock, which was pitching east. Then from the main tunnel a vertical raise was put up 2500 feet from the mouth of the tunnel, 338 feet, which struck lava. This was evidently too high, so a drift from the raise was started 300 feet above the main tunnel, which, after progressing 317 feet backward in the direction of the mouth of the main tunnel, struck the rim of the channel. The drift was continued 100 feet and at that point a winze was sunk into the channel, which was found to contain large, smooth, well-worn boulders and wash, but the water came in so rapidly as to make it all but impossible. Mr. Chappellet then went back to raise No. 1 and at 194 feet above the tunnel level started a drift back which is now in 100 feet. Should this drift be found to be beneath the channel a series of raises will determine its location, and, if too high, another drift will be run lower down.

There is not a more interesting feature in mining geology than a study of those ancient river channels. The above description of the discovery of a channel is a single instance; the discovery of the Mayflower channel, near Forest Hill, by Felix Chappellet Sr., is another of similar character. This latter was made some years ago, when the channel system of the Forest Hill divide was not so well known as now; but even to-day some of the best and most experienced mining engineers on the divide are sometimes at a loss, coming unexpectedly upon channels whose existence was unknown, and again failing to find a certain channel where it was calculated it should be found.

If the channels were all bedrock channels—that is, all of a contemporaneous time—the vexatious problem would be much simplified, but such is not the case. There are four periods of channel formation, including the recent—those of the first period, usually broad, with heavy wash, including numerous large boulders, and cutting into the underlying crystalline rocks. The main channel of the Mayflower mine is a type of channel of the first period. (See Fig. 1, on page 285.)

When these broad channels, which in places were 1000 feet wide, were still living rivers, volcanic disturbances occurred, which lasted doubtless many centuries, but which, geologically, are of one age—the Pliocene. These disturbances extended hundreds of miles along the Sierra Nevada mountains. They were characterized by the vast amount of material ejected from the volcanic rents. In various parts of the range these materials differed. In the region under discussion it consisted chiefly of andesitic fragments, ashes, and, doubtless, also vast quantities of mud. This volcanic ejectamenta covered thousands of square miles of territory, and, flowing slowly westward, filled the river channels in places, no doubt, to the tops of the neighboring hills, and possibly burying them from sight. Immediately the streams began the task of cutting new channels for themselves across this sloping and probably undulating plain of lava. While these channels appear to have been confined within certain broad limits, they did not follow the courses of the first streams. It would seem that the streams were now more numerous, narrower, and carrying large amounts of detritus derived from the freshly deposited volcanic material, cutting their ways rapidly into the soft lava rocks, until they had reached either the channel of the original stream beneath or cut into the bedrock itself, thus becoming gold bearing. Thus were formed channels of the second period. (See Fig. 2, page 285.) The channel of the first period is seen in the center, with a channel of the second period on either side. Fig. 3 illustrates a longitudinal section along a channel of the first period, channels of the second period having cut their way across it.

The channels of the second period had apparently no sooner cut their way into the older channels or underlying bedrock than they in turn were filled by further volcanic outbursts, which poured again from the crest of the Sierra Nevada; but the work of erosion was continued without cessation, and the channels of the third period were soon under way, their sinuous courses being determined by the inequalities of the surface. The channels of the third period only repeated the history of those of the second period. The fact that the channels of the second period, and again those of the third period, were able to cut through the great thickness of lava and even scour their ways down into the underlying bedrock, indicates what a vast time must have been necessary to accomplish this. Erosion was doubtless more rapid than at the present day, for the modern streams, though still hundreds of feet above the base level of erosion, do not flow as swiftly as then, nor do they carry the vast amount of sharp-cutting sand and rock fragments. Then, too, the bedrock is universally harder than the lavas, with few exceptions.

Channels of the second period cutting those of the first period, as in the center of Fig. 3, would at a lower point on its course deposit in its bed a body of gravel derived from the erosion of the channel of the first period, as may be seen in Fig. 4, where a channel of the second period is marked "upper lead." This deposit may occur in places directly above a channel of the first period, and in some instances follows such older channel for long distances. Where this condition obtains, it is quite evident that the rims of the channel of the first period had some influence in determining the course of the upper lead. Fig. 4, page 285, represents a channel of the first and also of the second period, and Fig. 5 illustrates channels of the first period, the Weske channel; the second period, the white channel in the center, and the third period, that on the right side, cutting into the Weske channel. Fig. 6 may represent a channel of the first period cut by a channel of either the second or third periods. Many channels of the third period contain only lava boulders and little or no gold.

The channels of the fourth period are the river courses of to-day. Fig. 7 illustrates the relation of the ancient system to the recent erosion. The forks of the American river have cut their canyons through 2500 to over 3000 feet of lava cap and hard bedrock since volcanic disturbances ceased in the Sierra Nevada.

The grades of the various channels are not at all uniform, some being much heavier than others, and, too, the grade of any particular channel varies from place to place, as may be seen in any modern stream. Fig. 8 illustrates the grades, as given by Ross E. Browne in his valuable contribution, "Ancient Rivers of the Forest Hill Divide," in the 10th annual report of the State Mineralogist of California.

In the mind of the writer there remains no doubt that throughout the ancient river period and lasting possibly till the present time there has been a slow upward movement of the entire Sierra region, extending from the crest of the range to the great inteior valley of California, and that this uplift was somewhat greater in Placer and adjoining counties than farther south in Calaveras, Amador or Tuolumne counties. There is much difference of opinion on this subject among those who have given the ancient river channels study, but there appear to be valid reasons for thinking that such uplift did occur.

Should the channel recently discovered by Mr. Chappellet prove to be the Dix-Greek channel, it will be a good thing for the mining industry in that section, as it would be the means of opening another large new mine which would give employment for years to several hundred men.

A glance at the map of the Forest Hill divide, made by Messrs. Browne and Hoffman, suggests that it might not have been unwise to have drifted directly up the old channel, where it might have been reached in the old Dix ground. This would have positively assured the identity of the channel. Should the newly-found channel eventually prove to be some other than the Dix channel, which may lie farther in the hill, then the Eureka Con. Co. have two channels to develop and work instead of one, as was the case in the Mayflower mine.

A Compliment from Colorado.

Among the periodicals devoted to the mining and milling industry, and publications of this class, the MINING AND SCIENTIFIC PRESS of San Francisco is absolutely without a peer. There is not even ground for comparison between the PRESS and others of its class. In fact, it is a class by itself.—Telluride, Colo., Journal, Mar. 4.

Experiences of a Working Miner.

NUMBER VII.

Written for the MINING AND SCIENTIFIC PRESS.

For several years the S—— brothers held a group of claims, doing enough work to hold them. No one ever accused them of having a good thing and a few people were actually surprised when they were offered and accepted $100,000 for their property—particularly at the offer. Soon after that the lonesome prospector's camp became a busy community. Buildings were rapidly constructed, including a fine residence for the superintendent, and a chapel. Scores of men were grading for a large mill, and a few weeks later a handsome structure had been completed, and then the hillsides re-echoed the thundering roar of 120 stamps. Two compact, neat-looking locomotives hauled long trains of rock from the mine to the mill. There was no better equipped nor more prosperous appearing camp in the country, but after a week or two of this prosperity cleanup day approached and it was suspicioned that the rock contained no gold, and the cleanup verified the suspicion. The works were closed, the mine caved, the locomotives rusted, and one day the mill burned. G—— is a desolate camp now. Its prosperity was short lived. This little bit of misplaced confidence cost one man over $300,000.

One bright day in the fall I tramped into L—— and found quite a camp. I had been there before when it consisted of a lonely prospector's cabin. Back on the hill were half a dozen claims, on each of which was a little development. Since my former visit Eastern capital had been interested and now the camp was a scene of busy activity. I found a number of men grading a road up C—— creek for the purpose of hauling in a second-hand 40-stamp mill, which was as good as new. To me it seemed that it might have been more sensible to haul a few hundred tons of ore to the mill—but this was a sure thing, so they all said, and the mill was hauled in and set up in first-class manner. A tramway, half a mile long, was built to connect with the mines; a bedrock drain was cut and numerous buildings erected; a ditch several miles in length was also part of the plan. I worked there a short time—nobody worked very long. It was an old, old story. The rock in the L—— mine was too low grade and too limited in quantity; the ore from the S—— claim was too base and would not amalgamate, and that from other mines didn't contain any gold. It cost nearly $100,000 to find these things out which might have been learned for $10,000 and some people would have been satisfied with even less than that.

A friend of mine told me not long ago of a little experience which came his way. A company purchased a mine and built a mill equipped with stamps and pans. It was known that the ore was difficult to treat, but after running the mill several weeks the mill was shut down, the gold cleaned up—what little there was of it—and the whole plant abandoned. After a time miners and others passing that way would look curiously at the old mill and sometimes they would step inside and look around. Some of them stepped as far as the assay office and cleanup rooms. Here were lying numerous useful little trifles, such as test tubes, beakers, graduates, scorifiers, annealing cups and a hundred other small articles such as may be found in and about mills. They were dust covered and doing no good, so one at a time these little things disappeared as the boys used to visit the mill from time to time, usually Sundays, when they had nothing else to do. No one was there to disturb them and no one seemed to care. This was fifteen years ago. Three or four years ago this property was bought by another company, the mill torn down and removed to a new site. When the false bottoms were pulled up out of the pans between $7000 and $8000 was discovered in hard amalgam underneath. My friend in relating this concluded by saying, "Imagine my feelings when I heard of this—and think of the chances I had."

A placer mine is a fine thing to own, even on the desert, when water can be pumped to it and it can be worked all year around, but if you own such a mine and have any idea of pumping water to it, be quite sure that your pumps are suited to their requirement, and having built the pumping plant, you are sure of getting all the water you need. At P—— is quite an area of gold-bearing ground, and the C—— river is but five miles away. There is a splendid fall and conditions are favorable topographically. The company that took up this proposition did so with a flourish and the newspapers contained columns of matter describing the great undertaking. I have seen the outfit. One should see it to appreciate it. The pipe line is five miles long and 10 inches in diameter. At the head of the line is a tank which will hold perhaps 3000 gallons—with this a big hydraulic mining operation was to be carried on. Possibly if otherwise equipped it might operate on a small scale, but the pumps will scarcely send enough water to the head of the line to keep the tank wet. It cost nearly half a million dollars to try this experiment, and I doubt if there is that much gold in all the placers of the district.

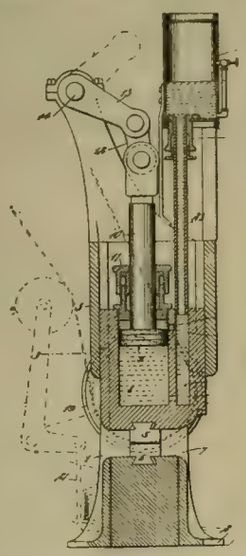
MINER.

Latest Mining and Metallurgical Patents.

Patents Issued March 7, 1899.

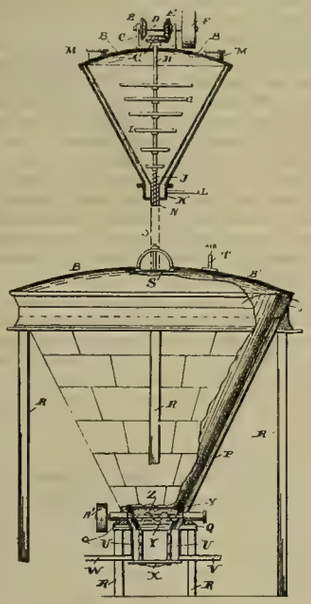
Specially Prepared for the MINING AND SCIENTIFIC PRESS.

POWER HAMMER.—No. 620,749; A. Dinkel, Auburn, N. Y.



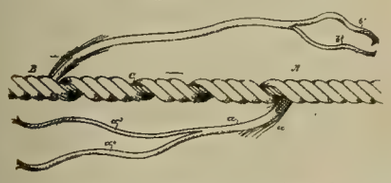
A sliding hammer head having a piston chamber for containing a liquid, a piston movable in the chamber and having its stem projecting through the upper end of the chamber; means connected with the piston stem for operating the piston, an auxiliary chamber communicating with the piston chamber at the upper and lower sides of the piston, and a chamber containing a liquid and a yielding cushion above the liquid thereof and offering a resistance to the liquid and consequently offering a resistance to the piston.

APPARATUS FOR TREATING ORES BY LIXIVIATION.—No. 620,660; Jos. Luce, Salt Lake City, Utah.



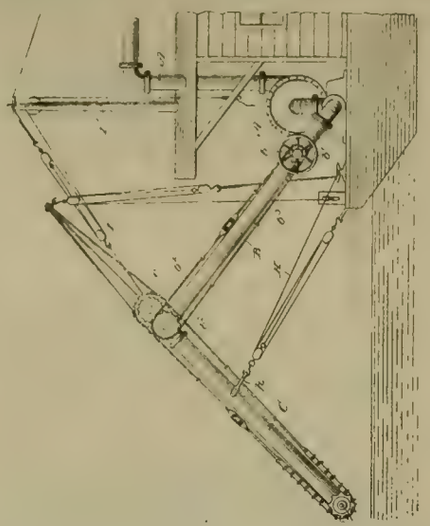
In a tank for the treatment of ores, a lining of asbestos applied directly to and covering the walls of the tank, combined with suitable supports placed inside of the asbestos, steam pipes supported in the tank and vertical layers of cloth arranged inside of the pipes; boards *E'* extending vertically in the tank inside of the asbestos and provided with suitable recesses and steam pipes placed in the tank, and supported in the recesses formed in the edges of the boards.

SPLICE FOR OLD WIRE CABLES.—No. 620,739; P. T. Christensen, San Francisco, Cal., assignor to the Washburn & Moen Mfg. Co.



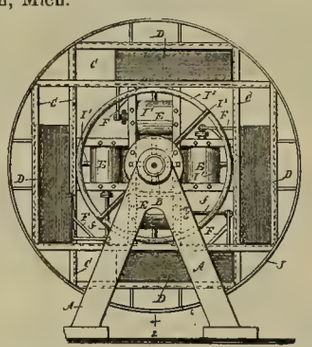
A rope or cable having ends united by a splice, consisting of opposing sections abutting together, each having projecting strands of different lengths and composed of a plurality of wires, untwisted and divided into groups, each section of rope or cable alternately laid upon each other from opposite directions and occupying the grooves or channels previously occupied by original undivided strands, and having their ends tucked under strands and secured.

DREDGING MACHINE.—No. 620,635; J. J. Bateman, Sunbury, Pa.



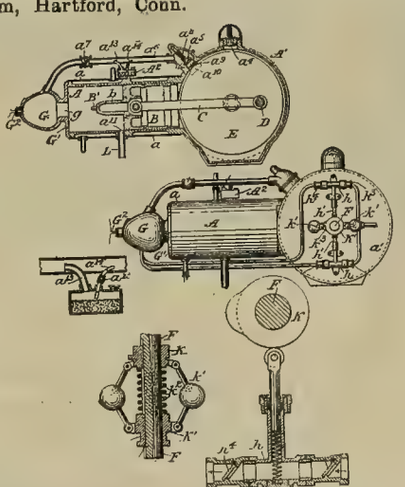
The combination with suction pipes connected to a centrifugal pump, means for adjusting or changing the position of pipes comprising three sets of tackles; the adjusting ropes thereof extending to the float, couplings which admit of varying the position of the pipe sections, a flexible agitator and screen positioned over the mouth or inlet opening of the suction pipe, connections extending therefrom to a gear mounted on the suction pipe, gears meshing with each other and gearing embodying flexible connections extending to a wheel which when operated will move the flexible agitator.

AIR COMPRESSOR.—No. 620,822; H. E. Anderson, Cheybogan, Mich.



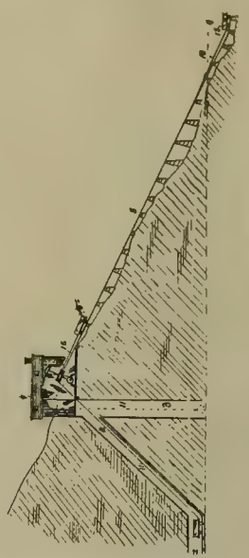
A frame having a central hollow shaft with two central partitions, guideways extending in direction of chords of a circle about shaft, weights in guideways having a limited reciprocation, an air compressor cylinder and a piston therein attached to each weight, discharge connections from the cylinders to one end of the shaft, cylinders having water chambers surrounding and cooling the cylinders, and water connections from chambers to the other end of the shaft.

EXPLOSIVE ENGINE.—No. 620,602; Hiram P. Maxim, Hartford, Conn.



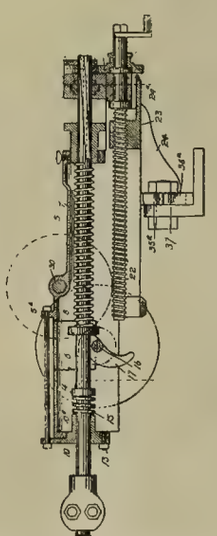
The combination with a cylinder, piston and explosion chamber independent of the cylinder and communicating therewith, the cylinder having an exhaust port arranged to be opened during the forward movement of the piston and the explosion chamber having a gas inlet, means for regulating the expansion of the gas from the explosion chamber to the cylinder; a check valve between cylinder and chamber and opening toward the chamber, of an air chamber in which air is compressed; a conductor communicating with chamber and with the explosion chamber; a valve controlling the air conductor, means to open the valve in air conductor as the piston approaches the forward limit of its stroke and means to admit the gas thereafter, the burned gases being expelled by the compressed air and the new charge being admitted to the explosion chamber in the rear of the body of air.

GRAVITY HOIST.—No. 620,801; A. C. Pratt, Carson, Nev.



The combination of the outer tramway with car moving thereon, a cable connected to car and to a motor reel, a shaft driven by reel and having a gear in position to engage gears on a countershaft, a clutch by which such engagement may be effected, and a drum on the countershaft having a cable connection to a hoist within the mine. The countershaft with two loose bevel pinions thereon in engagement with bevel pinion on the main shaft, a shiftable clutch on the countershaft by which engagement may be had with one or the other bevel pinion, and a drum on the countershaft having a cable and hoist connected thereto.

ROCK DRILL.—No. 620,847; M. C. Jackson, Denver, Colo., assignor to the Jackson Drill & Manufacturing Co.



Combination with the drill casing of a reciprocating drill shaft and power spring surrounding the shaft, of a crank shaft journaled in the casing, a gear fast on the crank shaft, another shaft journaled in the casing, a cam fast on the last-named shaft and adapted to engage a collar on the reciprocating shaft, a pinion fast on the cam shaft and meshing with the gear of the crank shaft, a pair of flywheels mounted on the extremities of the cam shaft, a feed-screw journaled in the casing, a guide track upon which the casing is mounted, the guide track being provided with a nut which the screw engages, means for feeding the casing to keep pace with the movement of the drill into the rock, (comprising a gear splined on the drill shaft, another gear splined on the feed screw and meshing with the gear on the drill shaft, the guide track being provided with a projection arranged to move the gear on the feed screw sufficiently to disengage it from the gear of the drill shaft by the time the screw has reached its forward limit of movement).

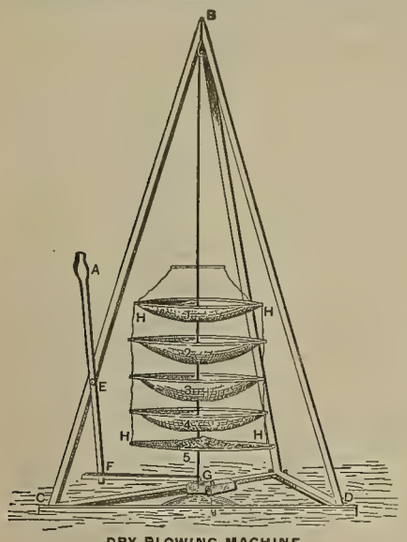
The Alluvial Deposits of Western Australia.*

NUMBER III.

By T. A. RICKARD, State Geologist, Denver, Colorado.

Another and more elaborate contrivance is exhibited in Fig. 4. It consists of a series of four trays, hung on a triangular frame *B*, *C*, *D*. The

FIG. 4.



DRY BLOWING MACHINE

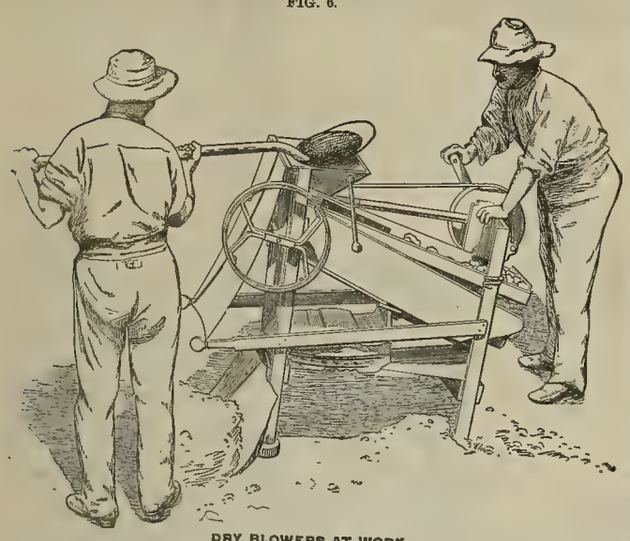
PLAN OF TRAY

trays are 22 inches in diameter. They are comparatively flat and have screen bottoms, through the center of which an iron rod passes to the eccentric *G*, which receives the required movement through the lever *A*, *E*, *F*, of which *A* is the handle. The trays are 5 inches apart and are held in place by wires *H*, *H*. The material to be treated is placed in the uppermost tray, which is a hopper pierced with inch holes. No. 2 has ⅝ holes, No. 3 has a 10-mesh screen and No. 4 has an 18-mesh screen. The lowest—No. 5—is flat and serves as a receptacle for the final product, which is dry-blown by hand, as heretofore described.

In these two contrivances no attempt is made to supplement the wind by an artificial air current. The next step is to use a bellows. Fig. 5 shows such an arrangement. It consists of a hopper *A* and a series of screens *B*, *E*, *F*, *G* and *H*. By turning the handle *M* the disk *K* is revolved; and this, by means of a belt, transmits its movement to the pulley, which shakes the screen *B*, *B*, through the eccentric rod *C*, and at the same time operates the bellows *D* through the disk *K*. Fig. 6 illustrates the machine when in operation.

When the material is placed in the hopper *A*, and the machine is set in motion, the large lumps run off

FIG. 6.



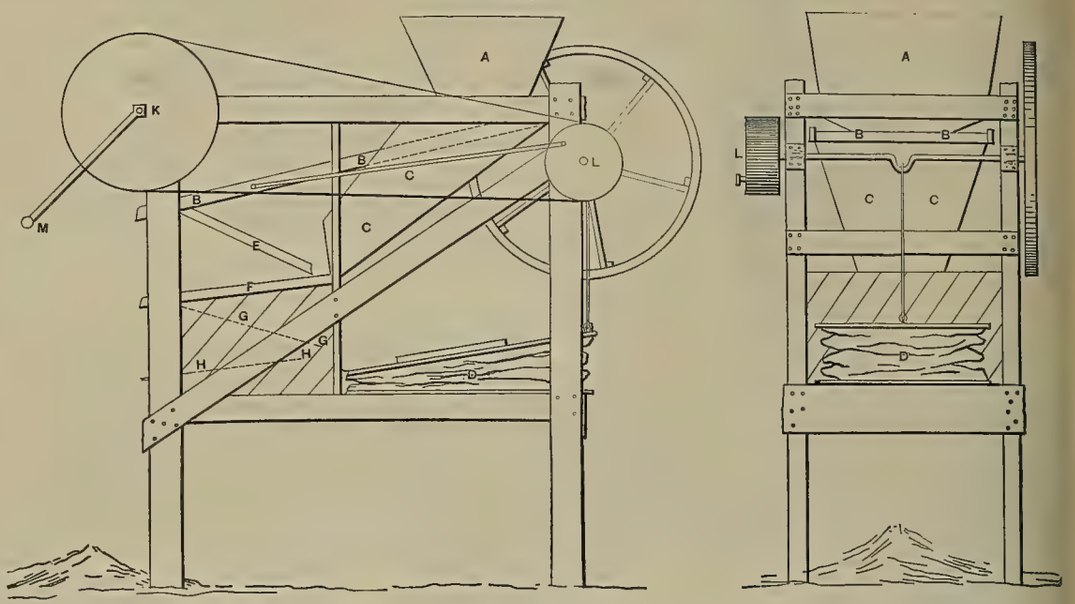
DRY BLOWERS AT WORK

over the grizzy or sizing screen *B*, *B*, the upper part of which is made of parallel wires $\frac{3}{16}$ inch apart and the lower portion of 8 mesh. The finer stuff falls down into the shoots *C*, *C*, and *E*, *E*, respectively, and reaches *F*, which is another (12 mesh) screen, supplied also with riffles. As it descends through the screens at *G* and *H*, both 18-mesh, the blast from the bellows keeps the material in agitation and aids the requisite separation between the particles of gold and the dust. The final product is panned by hand.

One of the most popular dry-blowing machines is that made by Steve Lorden at Freemantle. It is illustrated in Fig. 7. The essential parts are:

A. Feed hopper, sheet-iron bottom, punched with inch holes, hinged at A_2 and provided with riffles A_3, which arrest the heavier particles of gold, while the

FIG. 5.

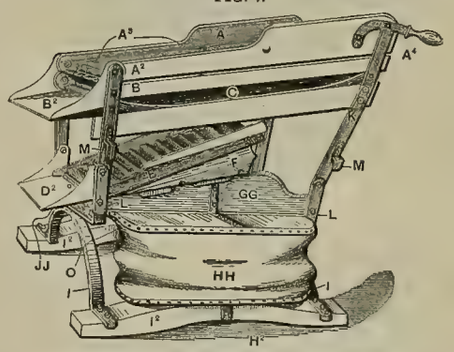


DRY BLOWING MACHINE
Scale 1″=1 Foot

coarse lumps of dirt pass out of the machine over the shoot B_2 and the fine stuff falls through into

B. Second hopper, which has riffles and smaller

FIG. 7.



LORDEN'S DRY-BLOWING MACHINE.

perforations, repeating the process. To examine this hopper the upper one *A* is sprung out of position at A_4.

C, *C*. Return shoots which lead the reduced material for further sizing upon the sloping screen *E*, which also has a series of riffles, and is placed directly over the air chamber *F*.

D_2 is a discharge shoot for the screen *E*. *G*, *G*, are air channels from the bellows *H*, *H*.

H, *H*. Double blast bellows, one on each side, which ride on carriers H_2, so arranged as to give the requisite play and to relieve the bellows from undue strain when in operation.

I, *I*. Rockers, bolted firmly to two foundation blocks, I_2, which form the stand, the only part of the machine that is not in motion. The curve of the rockers allows all dirt to fall away from the pivot pins *J*, *J*, by which the apparatus swings.

K, *K*. Standards, hinged at *L*, so that the machine folds up.

M, *M*. Brackets for the insertion of two poles, by means of which a couple of men can carry the machine conveniently.

The operator holds one handle at A_4 in each hand and rocks the machine, this serving simultaneously to put the bellows, hopper and screens all into movement. The machine weighs 124 pounds and has a capacity of from ten to fourteen loads (a load is roughly one ton) per day. The price at Freemantle is £16, or about $80.

The deposits exploited by the aid of these machines are of a generally patchy character and lie at the upper ends of the depressions formed where the surface slopes away from ridges traversed by the veins of gold-bearing quartz.

The prospector has an eye for the contour of the ground, and looks for the point where the rock surface disappears under the fragmentary overburden which he calls "made ground," as distinguished from the underlying "bedrock."

In his search he is usually guided by seeing the outcrop of quartz, marking a possible source of detrital gold and by the actual finding of specimens on the surface.

The distribution of the gold in these deposits reminds one of its position on a vanning shovel. It may be traced up to the outcrop which yielded it, or it may be scattered in the sand for half a mile; but the rich and only workable part of the deposit will ordinarily be found at a distance of 30 or 40 feet from the reef.

Underneath these patches of superficial gold-bearing detritus there are found partially consolidated accumulations, which are more extensive, and, quite apart from their greater economic value, are also of superior interest, because of their better defined geological features.

The Cement Deposits.—In the ordinary course of professional work I examined the two most important of these deposits at Kintore and Kanowna, respectively. Since then a third formation of a similar character has been opened up, also at Kanowna. This I happened to see when in the stages of early development, and before it had been extensively exploited.

The deposit of cement at Kintore was one of the earliest worked. It is situated twenty-three miles northwest of Coolgardie, on the road to Menzies. The West Australian Proprietary Cement Co. mined the ground with a success which was short-lived, because of the restricted quantity of material rich enough to pay the high costs of treatment. In four months 7335 ounces of gold was obtained by treating 4115 tons in a stamp mill, supplemented by cyanide vats.

Enough work has been done to disclose the character of the deposit. Under a thin covering of sand and dust there occurs a bed of kaolin, ranging from a couple of inches to a foot in thickness, and this overlies from 15 inches to 2 feet of "sand rock," which in turn gives place to the gold-bearing cement, which has an average thickness of 2½ feet. The last lies directly upon an irregular surface of decomposed granite.

The several layers composing the deposit are separated by seams of pipe clay, which, like the kaolin, are simply the product of the decomposition of the constituents of the granite, particularly the feldspar. The sand rock may be described as a coarse, incompletely consolidated sandstone or grit, consisting mainly of iron-stained particles of quartz, loosely cemented. The cement has a bluish-gray tinge, owing to the play of light on the quartz fragments. This, too, is not quite compacted, since fractures through the material do not break across the pebbles, which are harder than the clay binding them together. In this respect the cement differs, for example, from the South African "banket," to which it has been compared. From a distance the cement looks like a coarse sandstone and exhibits a rough-joint structure. The materials of which it has been made up have undergone incipient sizing, so that different layers of varying coarseness are distinguishable.

*Condensed from paper read before the Am. Inst. M. E.

The bedrock is granite, so softened by decomposition as to be mistaken by the miners for a part of the alluvial deposit. It is kaolinized to a depth which the neighboring mine shafts prove to reach a maximum of 130 feet. The surface on which the cement lies is marked by pot holes having a maximum depth of 2 feet and a diameter reaching to 3 feet. These holes are filled with cement, which is usually poor save at the rims, where some of the richest mill stuff has been obtained.

All the members of the deposit, from surface to bedrock, contain some gold, the kaolin being the poorest. The cement itself attains a maximum thickness of 5 feet. The richest parts occur in lateral embranchments from the main body of the deposit. The kaolin has become hardened and dried. It breaks like shale, and its true character is obscured by the down-filtering of red sand through cracks reaching to the soil overhead.

The deposit extends through a number of mining claims, and has been traced for a length of three-quarters of a mile. At the east end it begins as a narrow neck about 15 feet wide, and then enlarges steadily to 100 feet. Occasional bulges increase this width to a maximum of 250 feet. At the edge it gives place, as it thins out, to 2 or 3 feet of iron-stone gravel, carrying 3 or 4 dwts. of gold per ton.

The bedrock rises westward at the rate of 15 feet per 1000. This fact suggested that the origin of the gold-bearing cement was to be found in the reefs which were being profitably mined by the Sugar Loaf Co. The workings were 136 feet deep at the time of my visit in September, 1897. The veins traverse granite which has been kaolinized to 130 feet from the surface. They consist of white quartz and are narrow (4 to 12 inches), but they carry short shoots of very high-grade (three to ten ounces of gold per ton) ore. The gold occurs native, in flakes penetrating the cleavage planes of the quartz like a golden mosaic, and also in coarser particles, which, under closer examination, prove to be octahedral crystals with curiously rounded edges. A comparison of these veins and their enclosing rock with the material composing the cement deposit unquestionably indicates the derivation of the latter from the former. The cement carries gold which is exactly similar to that seen in the reefs; the quartz fragments in the alluvial are identical with the stone broken in the Sugar Loaf mine. In the cement occur particles of quartz showing gold. The loose gold in the cement has been but slightly worn, and the quartz pieces are rather subangular than rounded, so that they can hardly be termed "pebbles," and the deposit itself is better defined as an agglomerate than as a conglomerate. The binding material, the overlying layer of kaolin and the sand rock capping the gold-bearing stratum of cement all exhibit very clearly their derivation from a decomposed granite, similar to that which encloses the reefs and forms the bedrock of the alluvium itself.

The topography confirms this supposed relationship. The highest point along the major axis of the cement deposit is a very low ridge separating the workings of the Sugar Loaf from the alluvial ground.

Automatic Division of Irrigation Water.

Throughout the arid regions there are many irrigation systems where a certain stream of water, often varying in volume, is divided in varying proportion among the people entitled thereto. It is customary for the overseer to determine, in miner's inches, the amount at the head of the system and to measure out to each consumer along the line the number of inches to which he may be entitled. It is unnecessary to discuss at this point the various methods of measurement. Suffice it to say that where the water is flowing in open conduits or gravity pipes the irrigator near the head of the line is likely to fare better than the one at the lower terminus; for if the overseer be careless, or the users on the upper portion of the line piggish, the last man may be left dry as Sahara. It may be that the stream is the natural surface flow of some creek, in which case the evaporation along its tributaries during the heat of the day results in a decrease in the amount reaching the headgate of the system—frequently a loss of one-half. If the gates of consumers along the upper portion of the line be set so as to take continuously their maximum quota it is plain that the division is not equitable.

For the past five years there has been in operation at West Highlands, San Bernardino Co., Cal., a system which obviates these difficulties and permits the overseer to make his rounds on a peace footing. The consumers in the vicinity of West Highlands receive their water from the Bear Valley canal in a cemented ditch one mile in length. There are no consumers' gates along this line, all the water being delivered through the six lateral ditches, each a mile long, which lead away from it by a series of adjustable automatic weirs.

At the head of each of the first five laterals is a basin, as shown in the first engraving, from a photograph specially made for this article. It is virtually an enlargement of the main ditch and is about 12 feet square. Each of these weirs has two or more openings equipped with iron gates provided with doors which slide in lateral grooves. One opens into the main ditch and one into the lateral. In the weir shown the central gate opens into a flume supplying water to the ground immediately adjacent. All the openings in each weir are on a level with each other and when open the water flowing through them is of equal depth in all.

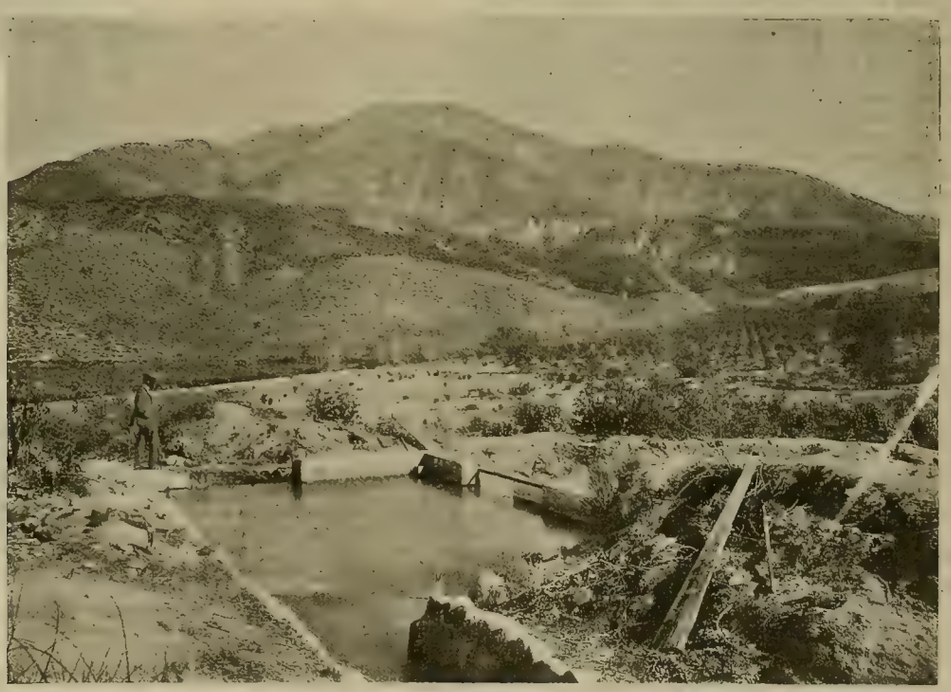
Division of water by this system is simple. The overseer starting down the line with say 300 inches, to be equally divided between the six laterals, goes to the first weir and sets the gate opening into the main ditch at its maximum width, which, in this instance, is 40 inches. The gate opening into the lateral he sets at 8 inches. Thus the main gate will take five-sixths and the side gate one-sixth of the water—250 and 50 inches, respectively.

At the second weir he sets the gates at 40 and 10 inches, respectively, and so on down the line. At the fifth weir, the last point of division, he has 100 inches to be divided between the last two laterals, and consequently sets the gates equally open. A hasp on the door is provided, at its loose end, with a peg which fits in any one of a row of holes drilled, at intervals of ½ inch, in the top bars of the front gate. A slot in the hasp fits over a staple above the one to which it is fastened. When the sliding door is set at the desired place, the hasp adjusted and secured by a padlock, meddling becomes difficult. The amount of water flowing may be determined by the open-weir table. An outlet under the main gate affords opportunity for sluicing out sand or sediment which may accumulate in the basin.

The schedule is so arranged that water is delivered to but one consumer in each lateral at a given time. Any increase, and likewise any decrease, in the amount coming into the system at any and all hours of the day automatically divides itself among all consumers.

The divide shown in the lower engraving, at the junction of two of the company's ditches, has a capacity of 2000 inches.

ADJUSTABLE AUTOMATIC WEIR AT WEST HIGHLANDS, SAN BERNARDINO COUNTY, CAL.



LARGE WEIR WITH DOUBLE GATES USED IN THE HIGHLAND IRRIGATION DISTRICT.

Commercial Importance of a Pacific Cable.

The submarine telegraphs of the world, and especially the practicability of a submarine telegraph across the Pacific, are discussed at considerable length in the January number of the "Summary of Commerce and Finance," just issued by the Treasury Bureau of Statistics. The statement shows that the submarine telegraphs of the world number 1500. Their aggregate length is 170 000 miles; their total cost is estimated at $250,000,000, and the number of messages annually transmitted over them 6,000,000. All the grand divisions of the earth are now connected by their wires, and from country to country and island to island the thoughts and words of mankind are instantaneously transmitted. Beneath all oceans, save the Pacific, the universal language which this system has created flows uninterruptedly, and man talks as face to face with his fellow man at the antipodes. Darkest Africa now converses with enlightened Europe or America, and the great events of the morning are known in the evening throughout the inhabited world. Adding to the submarine lines the land telegraph systems by which they are connected and through which they bring interior points of the various continents into instan-

taneous communication, the total length of the telegraph lines of the world is 835,000 miles, the length of their single wires or conductors 3,500,000 miles, and the total number of messages annually sent over them 365,000,000, or an average of 1,000,000 each day. Of the 170,000 miles of submarine telegraphs, about 150,000 belong to thirty-five companies operating the commercial cables, which number about 320; the remainder are mostly short lines controlled by governments, and connecting forts, batteries, signal stations, lighthouses, etc., the aggregate of government lines being about 1150 and their total length about 20,000 miles. In addition to this, the governments of the world hold about 80,000 miles of cable in stock for war purposes, ready to be laid at a moment's notice.

In the short half-century since the practicability of submarine telegraphy was demonstrated, the electric wires have invaded every ocean except the Pacific. Nearly a score of wires have been laid across the Atlantic, of which no less than thirteen now successfully operate between the United States and Europe, while three others span the comparatively short distance between South America and the African and south European coast lines. Throughout the Indian ocean lines connect the far East with Europe and America by way of the Red sea, the Mediterranean, the western coast of Europe, and the great transatlantic lines. The Mediterranean is crossed and recrossed in its entire length and breadth by numerous cable lines, and the "Mediterranean of America," the Gulf of Mexico and the Caribbean sea, is traversed in all directions by lines which bring its islands and colonies into speaking relations with each other and with South America, Central America, the United States, and thence Europe, Africa, Asia—the whole world. Along the eastern coast of Asia cable lines loop from port to port and from island to island, receiving messages overland from eastern Europe by way of the Russia-Siberian land lines and forwarding them to Japan, China, Australia, New Zealand, the Straits Settlements, Hongkong and the Philippines, and sending others in return. South America is skirted with cable lines along its entire border, save the extreme south, where they are brought into intercommunication by land lines. Along the entire coast of Africa cables loop from place to place and colony to colony, stretching along the entire circumference and penetrating the interior by land lines at various points.

Every body of water lying between the inhabited portions of the earth, with the single exception of the Pacific ocean, has been crossed and recrossed by submarine telegraph lines. Even that vast expanse of water has been invaded along its margin, submarine wires stretching along its western border from Siberia to Australia, while its eastern borders are skirted with lines which stretch along the western coasts of the two Americas. Several adventurous pioneers in Pacific telegraphy have ventured to considerable distances and depths in that great ocean, one cable line running from Australia to New Zealand, a distance of over 1000 miles, and another extending from Australia to the French colony of New Caledonia, 800 miles seaward.

The chief obstacle in the past to the construction of a grand transpacific cable was found in the fact that midocean resting places could not be satisfactorily obtained or arranged for, no single government controlling a sufficient number of suitable landing places to make this seem practicable, in view of the belief that the distances from which messages can be sent and cables controlled were limited. With landing places at Hawaii, Wake island, Guam and the Philippines, however, no section of a cable stretching from the United States to Asia and touching at these points would have a length equal to that now in daily operation between France and the United States. The length of the French cable from Brest, France, to Cape Cod, Mass., is 3250 miles, while the greatest distance from land on the proposed Pacific route would be that from San Francisco to Hawaii, 2089 miles, that from Hawaii to Wake island being 2040 miles, from Wake island to Guam 1270 miles, from Guam to Manila 1520 miles, and from Manila to the Asiatic coast 630 miles. While the depth of the Pacific is somewhat greater than that at which any cable has been laid, the difference between its depth and the greatest reached by cables in the Atlantic would be very slight, the cable recently laid from Haiti to the Windward islands being in 18,000 feet of water, while the greatest depth between San Francisco and Hawaii is 18,300 feet, and the greatest depth between Hawaii and Manila is estimated at 19,600 feet, though this estimate is yet to be verified by detailed soundings. Otto Krummel, who was the first to discuss the bathymatric data and calculate the area and volume of the various oceanic basins, puts the mean depth of the Pacific at 2160 fathoms, against 2040 for the Atlantic, in which cables have already been so successfully laid, and later researches and actual soundings, while they have developed extreme depths at certain points in the Pacific, have not, in the opinion of experts, been such as to warrant the belief that the depths along the proposed line would be considerably greater than those in which cables have been already successfully laid and operated.

The developments in construction, laying and operating of submarine cables and in their availability for general public use have kept pace with their extension throughout the civilized world. From a mere guttapercha-coated wire, the submarine conductor of electricity has developed in a half century into a great cable, having a central copper core surrounded by numerous layers of non-conducting material and protected by steel wire wound spirally about it, and in turn further protected by waterproof and insect-proof wrappings. From a steamer-towed, open barge, the facilities for laying have developed to a fleet of nearly fifty steam vessels, with every facility for laying, picking up, splicing and repairing the cable lines. From a speed rate of four words per minute, which was made on the first transatlantic cables, the speed of transmission has been accelerated to fifty words per minute, and even more than that with the automatic transmitters now coming into use with cable lines, while by the duplexing of the cables their carrying capacity is doubled. From a cost to the sender of $100 a message, which was originally charged on the first transatlantic cables, the rate from New York to London and the great cities on the continent of Europe has fallen to 25 cents per word. From several hours required for the transmission of a message and receipt of a response, the time has been so reduced that messages from the Executive Mansion to the battlefield at Santiago were sent and a response received within twelve minutes, while a message sent from the House of Representatives in Washington to the House of Parliament in London in the chess match of '98 was transmitted and the reply received in thirteen and a half seconds.

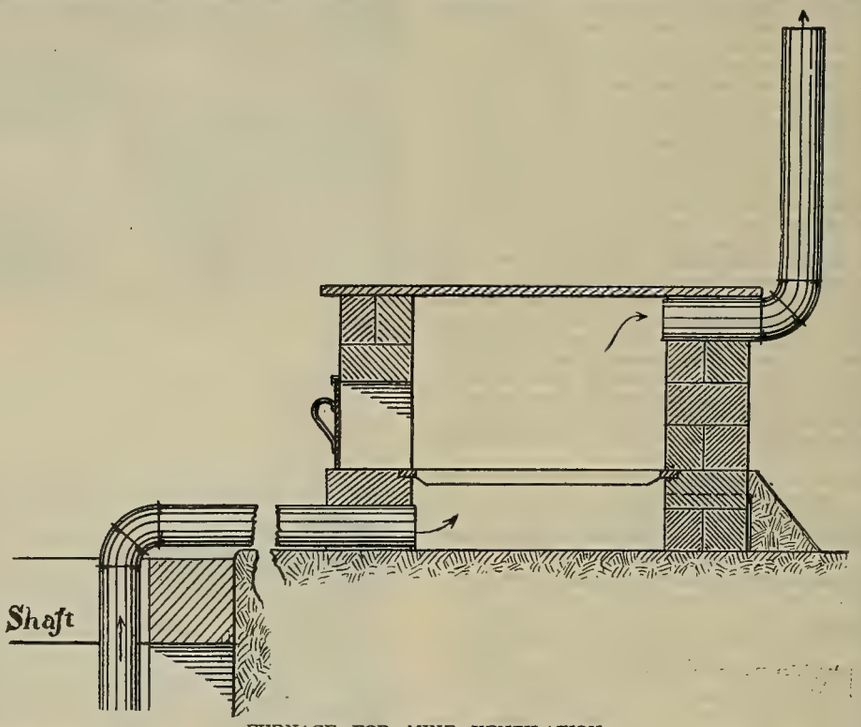
The effect of this ready and inexpensive method of transmitting thoughts and words from continent to continent throughout the civilized world is shown in the rapid development of international commerce since it began. The first successful cable lines between the United States and Europe were first put into operation in '66. In that year our commerce with Europe amounted to $652,232 269; in '76, $728,959,053; in '86, $896 911,504; in '96, $1,091,682,874; and in '98, $1,279,739,936; while our commerce with the whole world, which in '66 amounted to $783 671,588, had by '98 reached the enormous sum of $1,847,531 984.

With this evidence of the advantage of prompt communication between commercial centers desiring an interchange of their products, it may not be improper to call attention to the fact that the United States now obtains but a small proportion of the commerce of Asia, which it is at present only able to reach through the long and devious submarine and land telegraph lines across the Atlantic, the continent of Europe, the Mediterranean, the Red sea or the Persian gulf, the Indian ocean, land lines across India, cable lines again by way of the Straits Settlements, and thence along the Asiatic coast and among the islands of Oceanica. The commerce of the countries of Asia and Oceanica, lying commercially adjacent to the Philippine islands, amounts to more than $2,000,000,000 annually, their imports alone averaging $100 000,000 per month, or $1,200,000,000 per annum. Of this enormous market the United States at present obtains less than 6%, despite the fact that the imports into the countries in question are largely composed of the classes of articles produced in the United States and offered for sale by her manufacturers and merchants. With a direct cable communication across the Pacific, direct water communication through a Nicaraguan canal, and an increase in the number and capacity of American steamships, it seems not improper to suppose that a material addition might be made to the share obtained by the United States in the trade of that part of the world.

Cheap Ventilation in Small Mines.

Written for the MINING AND SCIENTIFIC PRESS.

Many small mines experience a great deal of trouble with powder smoke and foul air, particularly in warm weather. Ventilation may be vastly and cheaply improved in a variety of ways, one of which is the fire draft. This is accomplished by the construction of a furnace at the surface connected by pipe with the mine workings. The furnace may be built of brick or stone. When no more suitable material is at hand, rock from the dump may be used. Particular care must be exercised to make the furnace air-tight. The bricks or stone should be carefully laid with a liberal supply of mortar—sand and clay will answer, or any mud may be used. When finished, the outside should be treated to a coating of mud, to stop up all cracks. In constructing the furnace, a place should be selected far enough from the mouth of shaft or tunnel to be out of the way. If it is a tunnel to be ventilated, the furnace may be built on the hillside above it, and, if a shaft, any place near the shaft will do. When construction begins, first prepare a space for the pipe leading into the mine, and, putting the pipe in place, build around it. On the opposite side of the furnace, and level with the bottom, arrange an opening which may be closed or opened, when desired, for the purpose of removing ashes. This door must be kept sealed when there is a fire in the furnace. When the wall has reached a height of 10 inches, grate bars—iron bars of any sort—should be put in place. On one side, where it will be convenient, provide a door for the introduction of wood. The bottom of this door should be even with the grate bars. Continuing, provision should be made for the smokestack near the top of the firebox. For the top of the furnace one or more large, flat stones may be employed, one being better than two, and a heavy iron plate better than either. When completed, with pipes in place, the furnace is ready for work. After firing up, the smoke will quickly detect leaks, which should be plastered over with mud. It is very important to keep the doors shut tightly and to render the furnace as nearly air-tight as possible. The pipes should be not less than 5 inches in diameter, and the inside measurement of the furnace should be not less than 20x20 inches on the grate bars, with a height of 18 inches above them. In wet mines galvanized iron pipes are best, though in dry workings tin may be used for a long time. An enlargement of the pipe at the end nearest the face of the tunnel or bottom of shaft is an advantage. The pipe, in 10 foot sections, should be carried as near the face as possible with safety. The pipe may be protected from blasts by the use of plank or lagging. This simple and cheap device will greatly improve ventilation in quite extensive workings. The better the construction of the furnace and the larger its size, the more perfect is its operation. The smokestack should be carried up several feet above the furnace to secure good results. The accompanying cut illustrates a vertical section of the furnace, showing doors, grate and pipe.



FURNACE FOR MINE VENTILATION.

Mining Summary.

ALASKA.

A strike in the Sea Level mine, near Ketchecan, southeastern Alaska, is reported. A vein of $40 ore has been uncovered.

United States Consul McCook writes from Dawson City: "Investors should be careful of mining properties offered for sale, particularly in some sections of Alaska. Of the many who came here last spring and summer, hundreds drifted down the Yukon and located at Forty Mile, Eagle City and Star City. I am informed that there are many schemers there who get up miners' meetings, elect their own recorder, jump claims already recorded, get their men to give them receipts as record papers and issue prospectuses of water rights, all apparently in conformity with United States mining regulations. They have organized companies, their scheme being to sell their so-called water rights to the public. No one should buy anything until perfectly satisfied. There will be any number of valueless claims offered by promoters."

A Juneau dispatch says that the property of the Pande Basin Gold Placer Co. is leased to F. P. Voorhees for five years. The rental is stated to be $2,650,000, and $20,000 is alleged to have been paid down. In Pande basin is the lake out of which was drained last January 61 feet of water through a tunnel to expose gold bearing sand on the beach. The report sounds well, but lacks confirmation.

A correspondent of the Victoria *Times* says a large number of claims on Pine, Spruce and other creeks are thrown open, and the price is very low. Benches on Pine creek are offered at from $100 to $250, but no sale for them. There have been no sales at all, everyone awaiting the Gold Commissioner, who had not arrived up to Feb 26th. The rush had not commenced, although a few men were coming in every day. He saw a few specimens of quartz. No assays had been taken. It is a fine country. The thermometer ranges from zero to 20° below. The coldest day was on Monday, Feb. 28th—52° below.

ARIZONA.

At the Yarnell mine, near Prescott, a 10-stamp mill will be built.

At the Lowell and Arizona mines at Bisbee Supt. Fenner has raised through an old shaft to the surface. The shaft is double compartment. A new 25 H. P. hoist is to be put in at once. This property joins the Copper Queen, the output of which is 120,000 pounds of copper daily. The formation is limestone, intersected with porphyry dykes.

Nearly $100 was recently taken from dry gulch diggings near Prescott, supposed to have come from a blind lead. There are numerous gulches near Prescott which have been rich in gold where no veins have been found—one in particular, four miles south of Prescott, from which it is said $70,000 was taken, and no veins are known to cross it.

The hoisting plant on the Blind Goddess, at White Hills, has been removed to the Norma, in the same district.

Cinnabar occurs, with hematite in rhyolite, thirteen miles southwest of Prescott. Only superficial work has been done on the claims.

It is locally rumored an English company has purchased the Ray mines, on Mineral creek, and will build a railroad thirty-five miles to the Southern Pacific road at Picacho.

H. W. Blaisdell has taken hold of the King of Arizona mine and will make an effort to secure water there. Failing in this, he will place a pump on the Colorado river and pump to the mine, forty miles.

Republican: The Mammoth M. Co., in Pinal county, will put in an electric plant to run its 50 stamp mill and the 30-stamp mill of the Mohawk mine. The Mammoth mill will be enlarged by the addition of fifty stamps. The transmission line will be fifteen miles long.

—A strike has been made at the Oriole mine, at Old San Domingo, eight miles from Wickenburg; F. C. White is Supt. The company has sunk a shaft to a depth of 200 feet. There are now 800 tons of ore on the dump. The new strike was made in the west drift, disclosing a vein 2 feet wide, assaying more than $30 a ton.

Globe *Silver Belt*: C. E. Gunn has taken a lease on the New York and Chicago mines, belonging to the Old Dominion Copper M. & S. Co., situated near Bloody Tanks. The ore will be smelted by the Old Dominion Co.

Prescott *Courier*: The Hidden Treasure mine, six miles from Bumblebee, has shipped five tons of ore to the Prescott sampler, worth $100 per ton.

CALIFORNIA.

Amador.

Sinking is to be resumed on the Spagnoli mine at Pioneer.

Dispatch: It is reported that a large body of low-grade ore has been opened on the 1700 level of the Oneida mine, two miles north of Jackson. Drifts are in some distance north and south on the vein from the crosscut where the discovery was made.——It is reported that ore has been found in the shaft at the Amador Queen No. 2 mine, the ledge extending across the width of the shaft. The rock is said to show free gold and sulphurets.

Calaveras.

Rich rock is being mined in the Colliersville district, six miles east of Murphys. Some of this rock looks like "black granite" and would scarcely be thought to contain gold, but is liberally sprinkled.

The Sheep Ranch mine at Sheep Ranch is to resume operations.

The Gwin mine has declared another dividend of 25 cents per share and there is $12,000 still remaining in the treasury. The shaft is to be sunk an additional 200 feet, making a total depth of 1600 feet. Large ore reserves are blocked out between the 1000 and 1400-foot levels. This is one of the old, long-abandoned mines of California which after years of success remained idle for many years.

Prospect: The Big Horn, now known as the Taylor mine, two miles north of Murphys, is being worked by Mr. Tucker, as representative of a Fresno company.——At the Central Hill mine near Murphys piping is in progress, but the available part of the channel is nearly exhausted. When the tunnel was run through bedrock from Douglas Flat it was supposed the Central Hill Co. would have a large amount of valuable channel, but it was found that a later channel whose existence was unknown had cut out a large portion of the Central Hill channel, and the drain tunnel was too high to drain the new channel which crosses the Central Hill at nearly a right angle.

Del Norte.

J. A. Johnson of Crescent City has shipped three tons copper ore to the Selby Smelting Works, San Francisco.

Del Norte *Record*: The beach miners at the mouth of Gilbert creek near the Oregon State line had their dam carried away by the freshet and a heavy sea that prevailed. M. Burnett says it will take several weeks to repair the damage.

El Dorado.

Placerville *Democrat*: A rich body of ore has been discovered at the Omo mine, eight miles east of Fairplay, which assays $19 per ton. It is free milling and fully 85% of the assay will be saved. Twenty men are employed at the mine, and five stamps have recently been added to the mill, making ten stamps. The main tunnel is in 1000 feet, with 350 feet of backs.

Inyo.

Bishop *Register*: Harrison, Goldsmark & Co. have their tramway ready to start up——Emerick & Dover will have a mill at Stone Corral in two weeks, the machinery being now at Johannesburg.——Parties who bought out Lambert, Grey & Tate at Anvil Springs will have a mill on the ground in less than a month.——A. Williams has bonded his property at Tuber for $20,000.

Lake.

A rich strike of cinnabar is reported from the Crystal Quicksilver M. Co.'s mine.

The Crystal Quicksilver M. Co. say that ore assaying $400 is being taken out.

Lassen.

A rich strike is reported from the Idaho mine on Hayden Hill. The hill is a network of veins and some of the mines in past years have produced very rich ore, notably the Juniper.

Madera.

Mining experts have been making an examination of the old copper mines at Buchanan, and also on the north side of the Chowchilla, in Mariposa county. These mines are in mica schist and show large bodies of low-grade sulphide ore.

Mariposa.

(Special Correspondence).—Experts Jennings and Mein spent most of last week examining the Mariposa grant in company with Supt. Ludwig and several old-time employes of the property. Their visit has added some extra strength to the annual spring rumor that "something is going to be done on the grant now."

A mill will probably be placed on Capt. Ward's Spencer mine at Whitiocks. Development work is uncovering a satisfactory ore body.

Galey & Co. are cresscutting to the Mother Lode at the 200 level of the Murphy mine. Their 6-stamp mill at the Porter is nearing completion and sinking is in progress on the Keystone shaft.

The Montana M. Co. has surrendered its lease on the Louisiana, which is temporarily closed. Later in the spring a new shaft and much other work will be started and deeper exploration carried on.

The Merced Co. is taking some rich specimen ore from the 600 and 700 levels of the Mary just now. A crosscut from the lower workings through the entire formation has developed a hanging-wall vein of considerable size and good appearance, but as yet undetermined value. Were he not hampered by the great expenditures incurred by the former management, Supt. Mills would be able to make a notable dividend payer out of the Mary. The mill is crushing from 100 to 125 tons per day and reputed to be saving about $10 per ton. Engineer McDonnell is making surveys for the company along the Merced river in search of a water power.

H. H. Clark is running the steam arrastra on the Alice Clark, a mile north from Coulterville. Some good ore is coming out and a sale is pending to Chicago capitalists.

Good ore is reported from the Champion at Pino Blanco.

F. A. Brown has sold his Lost Friend mine at Horse Shoe Bend to Hutchinson Bros. of Oakland.

Bear Valley, March 14th, '99.

Gazette: A. H. Ward is having 100 tons of ore crushed from the Spencer mine, six and one-half miles north of Mariposa.

Nevada.

The Superior Court has granted the application of the W. Y. O. D. G. & S. M. Co. for disincorporation.

The arrastra on the Sazerac drift mine, at Rough and Ready, has been started up.

The Eastern Star mine in Willow Valley district has been bonded by Voyce & Jones, who are now opening up the property. A ledge of quartz 2 to 4 feet in width was struck there years ago and ore taken out.

Nevada City *Transcript*: W. H. Weldon of Grass Valley will put a hoisting and pumping plant on a quartz claim extension of the Massachusetts Hill mine, near Grass Valley.

Nevada City *Transcript*: Sinking of the shaft in Phenix mine near Nevada City is progressing. Some rich ore is coming out.

Placer.

A 3-foot copper ledge is being worked near Lincoln. Twenty men are employed.

E. Chase and W. Scadden were killed last week in the Three Star mine at Ophir by a blast charged by the day shift which failed to go off at the proper time.

The Drummond mine near Forest Hill, which has been working under bond for some time past, has been shut down and the air compressors removed.

Lessees are working the Dardanelles drift mine near Forest Hill, crushing the gravel in a stamp mill at the mine.

Placer *Herald*: The Mayflower drift mine, near Forest Hill, is employing fifty-five men. All the work is being done on the Orono lead, and paying well. The mill and compressor are run by steam. The company is figuring on putting in an electric plant. In the near future a tunnel will be started to open the Andy Steel claim, which was rich on the same lead above. Work is going on at the Bartley mine, Dutch Flat. Its channel is 1000 feet wide. The company has no impounding dam. Wm. Stuart is in good paying ore at the Caledonia on the Middle Fork.

Riverside.

Antimony has gone up in price recently. There is a deposit of high-grade antimony ore about four miles southwest of South Riverside in the brush-covered hills, upon which little work has been done. The rocks of that section are largely eruptive and intelligent prospecting may discover a good mine.

Numerous claims have recently been taken up in the Eagle mountain district, forty miles northeast of Walters station, in the Colorado desert.

The Good Hope mine, three and one-half miles southwest of Perris, is working about a dozen men. The tailings are being treated by the cyanide process.——The Santa Rosa mine tailings, six miles west of Perris, are also being treated with cyanide, it is said, with good results.

There are a number of small rich veins lying in the granite hills west of Perris, about the Santa Rosa and near Gavillan which were worked years ago by Mexicans, the ore being ground in arrastras. None of these mines have deep workings. At the first sign of a pinch they have been abandoned, no effort being made to learn whether the veins would open out in depth again; but as they do so longitudinally, it is not unreasonable to suppose that they will do so in depth. The ore is high grade, and most of the veins dip at low angles.

The shaft at the Riverside mines is to be sunk 150 feet additional, making 450 feet.

Winchester *Recorder*: Work has been resumed on the Utica mine, twelve miles west of Winchester, and the development of this property will go on steadily. The owner, C. H. Briggs, will build a cyanide plant of thirty tons capacity.

Shasta.

Trinity *Journal*: The Iron Mountain Co. at Keswick has put in a steam shovel and contemplates putting in a shovel with each of its roasters.

Sierra.

Mountain *Messenger*: M. Pinney says the Mountain mine and mill has closed down for a short time in order that some needed improvements may be made to the mill.——M Copeland has reduced his force at the Triple Pocket mine, in Slug canyon, owing to the fact that more ore was being produced than the mill could crush. The mill is kept running night and day with Geo. Black in charge.

Siskiyou.

Siskiyou *News*: The unworked portions of the old Hibernia mine on Eddy's gulch, Salmon country, is being developed by R. L. Fagundes.——Nearly all the placer mines along the Salmon have water enough to work with.——The hydraulic claim of Brown, Hammer & Co. has started up.——The tunnel at the Commodore mine on Barkhouse creek is in 500 feet and it is expected to cut the ledge at a depth of 300 feet.

Yreka *Journal*: There is 10 feet of snow on the Salmon mountains, with storms every day on the high peaks, which will supply the miners of Quartz valley, Mugginsville, Oro Fino and vicinity with plenty of water during the coming summer.——The miners at the Greenhorn Blue Gravel mine have reached paying gravel in the caved-in drift, and are taking out considerable gold. A force of forty men is employed.——Some fine prospects of gold have been found in the mountains between Gazelle and Scott valley. Pieces of quartz taken out show free gold, and claims have been taken on the East Fork and on Willow creek.——Kingery & Co., working a ledge at lower end of Scott valley, are getting prospects from their quartz ledge.

Tuolumne.

(Special Correspondence).—The Rising Sun mine, at Arrastraville, is cleared of water and timbered where found necessary. They are now sinking a winze in lower level, 135 feet from main incline shaft. In the winze a vein 20 inches wide is found, showing galena and arsenical sulphurets. The quartz also shows free gold. The country rock is intersected by seams of quartz that prospect well. G. L. Tomkins is Supt.

Arrastraville, March 15th, '99.

The Crystalline mine near Table Mountain and 1½ miles northwest of Jamestown has been purchased by a Scotch syndicate. The price is reported to have been $250,000. The mine is developed by numerous drifts, crosscuts and shafts. F. Bainville will have charge of the property.

All of the surplus stock of the Boston & Tuolumne G. M. Co. has been taken by a Boston syndicate. The officers are: President, L. Auerbach; secretary, A. N. Winslow; treasurer, W. Jones. Its mines are at Big Oak Flat, adjoining the Longfellow. Three shifts of men are at work.

The new mill of the Bown Mining Co. near Tuttletown is about completed and will be ready to run the coming week.

Lack of water is still the cause of numerous mines lying idle in this county.

Telluride ores occur in some of the quartz veins of Big Oak Flat in granite formation. The quartz is crystallized in part and usually of milk-white color. Iron, lead and zinc sulphides also occur with the tellurium.

The new north tunnel of the Turner Flat gravel mine struck bedrock at 25 feet and no gravel. A third shaft and possibly a series of shafts will be necessary to determine the exact location of the channel. The work done through shaft No 1 was all on the rim, though considerable gold was obtained.

Sonora *Independent*: There are at Big Oak Flat in active operation the Longfellow, Gold Syndicate, Limited, the Mack Consolidated, Pauper's Dream, Little Giant and Tuolumne.——A new mill for the Trio mine near Jamestown and one for the Hazel Dell group near Soulsbyville will soon be built by the Mother Lode Development Co.——The mill at the Star mine, two miles from Columbia, has been closed down on account of the scarcity of water. Men are still at work in the mine.

Union-Democrat: The Newcomer mine, fourteen miles north of Columbia, has three veins, which are opened by several tunnels, shafts and drifts. There are about 200 tons of ore on the dump.

Tulare.

The gravel hills on the White river are said to be gold bearing.

Porterville *Enterprise*: The mines of White river are being diligently developed. Nearly all interested state that the prospects of their respective mines are most encouraging.

COLORADO.

The Denver mint receipts for January were $1,691,106 98, a gain of $260,876.58 over January of 1898. The February receipts this year were $1,745,463.53, a gain of $293,103 23 over February of 1898. The total receipts for the two months were $3,436,570.51, a gain of $557,979.21 for two months, or over half a million dollars.

BOULDER COUNTY.

Ward *Miner*: The Big Five wants bids for driving the Niwot tunnel 2000 feet—a mining tunnel of greater distance than any heretofore in the State.

Denver *Times*: The Sedalia copper mine, two miles from Salida, was sold on March 9th to Boston and New York parties for $60,000; B. T. Brooks has been retained as Gen. Mgr. at this point. The company will build a smelter.

Denver *Mining Record*: A strike has been made in a 100-foot shaft in the Gillard mine. It shows considerable free gold.

Boulder *News*: A strike of ore is reported on the Longfellow mine at Jimtown, owned by I. Berlin, and now worked by leasers. There is a 14-inch vein of ore which ran 2200 ounces of silver and one of gold to the ton——The St. George mine on Lee hill, Sunshine, is down over 100 feet, and in ore that is beyond the necessity of assays. The last tested went into the thousands.

EL PASO COUNTY.

Owners of a large tract of the sandstone belt near Trout creek recently visited their property. A test of several tons of the sandstone will be made at the Florence cyanide works. Tests have already been made at the Spence and Frisco mills.

A rich strike is reported to have been made at a depth of 30 feet in a town lot in the Hayden Placer addition to Cripple Creek. The vein is 5 feet wide, carrying gold, silver, copper and lead.

Victor *Record*: The applications of the Roxana G. M. Co. to patent a portion of the land from which the Isabella G. M. Co. is producing ore at Cripple Creek, have been denied in United States Land Office. The decision states that the "locations are invalid in both form and subject."

FREMONT COUNTY.

(Special Correspondence).—The Cripple Creek Beam M. Co. now have control of one of the cyanide mills at Florence and are making changes therein to adapt it to their method of reduction, and it is stated it will be made equal to 100 tons capacity per day.

Florence, March 10th, '99.

GILPIN COUNTY.

Mining Record: The old Stewart mine, five miles west of Black Hawk, on Stewart hill, will soon be operated. This property has been closed down since '74. The original owners were Boston capitalists, who are again in charge. Prof. E. C. Lindemann will put men at work.

Republican: One of the most promising of the new properties in Gilpin county is the Notaway. This property was taken three years ago by a Chicago company. The shaft is now down 400 feet.

Central City *Register-Call*: For the month ending Feb. 28th there were shipped 203 cars of ore, aggregating 3654 tons, which represented the shipments of smelting ore and concentrates to the Denver and other smelters during that month.——The Great North Downs M. Co. is sinking the shaft on the Moyle claim, on Swede hill, with air drills. J. V. Thompson of Black Hawk is Supt.——The Fisk mine employs sixty men, and the daily shipments now average sixty tons milling and smelting ore.

GUNNISON COUNTY.

Marble *Times*: The Copper Queen M. Co. has let a contract to extend the main tunnel, near Gothic, 200 feet, which will give it a total length of 500 feet.

HINSDALE COUNTY.

Record: A discovery of telluride ore has been made in the Clara L., in a porphyry dike 50 feet in width. It is said to be a continuous streak of petzite ore, varying from 2 to 6 inches in width.

LAKE COUNTY.

(Special Correspondence).—A force of 125 men is now employed on the Moyer Placers and Sierra Nevada groups of the Iron-Silver M. Co. at Leadville. The production runs from 400 to 600 tons per month of iron sulphide

ore, carrying values in gold, silver and lead, the smelters paying for the iron also.

Leadville, March 11th, '99.

A bad cave occurred in the Bon Air shaft, at Leadville, on the 9th inst., imprisoning two men. Within a few hours after the beginning of the cave, 520 bales of hay and straw were lowered into the shaft in the effort to stop further caving. Two-hour shifts were set at work to make connection with the Starr shaft to liberate the imprisoned men. Communication with the imprisoned miners was established by means of the water column pipe which was shattered at the proper point by letting dynamite down from the surface and firing it by electricity. Light and provisions were sent to the men. A shaft is being sunk parallel with the caved shaft. It is thought the men will be reached within a day or two.

Leadville *Miner*: Lessees of the Fanny Rawlins on Breece hill have opened a large amount of ore carrying gold and silver and 8% copper.

MESA COUNTY.

Grand Junction *Sentinel*: A $40,000 mining sale in the Unaweep country to Denver parties is reported. The properties are the Nancy Hanks, one of the early discoveries of that section last year, and which has been producing regularly since, the Jack Pot, Anna and Last Chance.

MINERAL COUNTY.

Several hundred pounds of powder exploded at the Commodore mine last week, killing four miners.

San Juan *Prospector*: The Nelson tunnel at Creede is in 1500 feet on the crosscut and 6000 feet on the vein.

RIO GRANDE COUNTY.

San Juan *Prospector*: The Golconda tunnel at Summitville is in nearly 100 feet. It has been found necessary to timber portions of the tunnel already passed. It has a grade of 4 inches in 100 feet.

IDAHO.

Eighteen miles northeast of Cuprum are the Carbonate Hill mines, in what is known as the Mountain View district. The veins are of good size and carry gold, with iron sulphides.

The Harvest M. Co. has been incorporated by E. T. Woolley, B. H. Goddard, B. P. Critchlow, R. A. Garner and J. D. Stratford of Ogden, Utah; D. J. Davis, J. P. Freeze, A. H. Woolley and L. S. Simmons of Salt Lake, Utah; H. S. Woolley of Paris, Idaho, and K. P. Plowman of Boise, Idaho. The property includes the Washington group of claims, in Gambrinus mining district, in Boise county.

The Gem mine will resume work within a short time. It has been closed since the summer of '97. The first work will be to pump out the mine, which will require some time, and a new hoist will be added. The Mammoth M. Co. is using the Gem mill. The Mammoth owns a millsite and water right just below Wallace, and the company contemplates building one there.

Grangeville *Free Press*: It is supposed that the extension of the Buffalo Hump has been discovered at Mallick district, on Salmon river. The ledge is 100 feet wide and shows up free gold. There are six claims located on the lead, which runs up from about four miles from the river and to within four miles of the Big Buffalo Hump group. The Grand Prize shows up best. It is here the free gold has been found.

Idaho *Statesman*: The following computation is made of the output of Cœur d'Alene mines for '98 by C. D. Porter: Bunker Hill & Sullivan, 26,400 tons; Helena-Frisco, 22,500; Morning M. Co., 16,280; Tiger-Poorman, 15,350; Standard, 13,460; Empire State of Idaho (Last Chance), 9650; Mammoth, 7000; Milwaukee, leasers (Gem), 850; Hecla, 300; Yankee (Blake Bros., Osburn), 100; Colwyn, 60; miscellaneous shipments, 500. Total, 112,500 tons.

De Lamar *Nugget*: A strike has been made on the fifth level in the mine at Flint, where the ledge has widened from a few inches to 2 feet of ruby ore, assays showing 500 to 600 ounces silver.

Toronto *Globe*: C. Sweeny of Spokane has already placed orders for $150,000 worth of machinery for the Big Buffalo mines.

MICHIGAN.

Rat Portage *Miner*: The report published of the gold vein discovered in 62-16, near Tower, met with ridicule and doubt; later developments prove that the strike is richer than the parties interested thought. Several pieces of rock from the vein recently assayed show an average of $26 to the ton.

MINNESOTA.

It is reported that copper has been found near the mouth of Knife river on the north shore of Lake Superior thirteen miles from Duluth.

MONTANA.

Neihart is to have a 100-ton concentrator.

The Granite mine, near Phillipsburg, is to be rehabilitated and the Bimetallic mill started.

Spokane *Chronicle*: A company has been organized in Spokane to work placer ground in McFarland gulch, near Missoula. The company owns two and one half miles of the bottom of McFarland gulch, which runs into Quartz creek, a tributary of the Missoula river. The gold found in the gulch is coarse, no precaution to save fine gold being necessary.

Clancy *Miner*: W. D. Ross, who has discovered a mine near the head of Lump gulch, will build a stamp mill the coming spring.

Helena *Independent*: The Belmont mine at Marysville, the first producer in that camp, is being successfully worked, the ores being treated by the cyanide process.

Spokesman-Review: The Leslie Copper M. Co. is preparing to work a group of ten claims on the Montana side of the Bitter Root divide. The claims have been held for years, during which time there has been several thousand dollars spent in development work. The company proposes to run a long tunnel which will cut veins in depth. The mouth of the tunnel will be less than a mile from the Northern Pacific track, which permits the laying of a spur direct to the tunnel site.

Butte *Intermountain*: The Butte copper mines are not increasing their output, notwithstanding the high price of copper.

NEVADA.

A rich strike is reported from the Magnolia mine at De Lamar.

The Grand Prize mine at Tuscarora is to be reopened.

The sulphur mine near Humboldt is in possession of a St. Louis firm, who intend to work the mine.

Virginia *Chronicle*: During the year '98 two mining companies in White Pine county filed reports of their net bullion product. One reported a cash balance of $4829 above the cost of production, the other 47 cents.

Winnemucca *Silver State*: The Pueblo mine on the State line between Nevada and Oregon, 115 miles from Winnemucca, is running steadily, about eighteen tons of ore being crushed daily. The rock is free milling quartz.

Virginia *Chronicle*: The directors of the Occidental M. Co. at a recent meeting decided to ask the Chollar and Potosi mining companies to resume work in the Zadig drift, which will connect the Brunswick lode with the Sutro tunnel. It is calculated that it will cost $10,000, to be divided up among the three companies, the Occidental people waiving any claim for the money already spent in running this drift. The distance is 2100 feet, of which the Occidental has already covered 1000.

Walker Lake *Bulletin*: L. E. Hanchett has purchased the Davis property in Fish Lake valley and will erect an electric power plant for mining and milling at the Silver Peak mines.

Mohave *Miner*: Forty tons of machinery await transportation to El Dorado canyon for a cyaniding plant to work tailings from the El Dorado canyon mill. The plant will handle fifty tons per day. E. G. Eckis and A. E. Vandercook will haul the Dodge pulverizer from the C. O. D. mine to the canyon. Mr. Vandercook has charge of the chemical department.

NEW MEXICO.

Several years ago Kingston was an active mining camp with a large silver output. The rich ore bodies near the surface were exhausted, the low-grade material being thrown on the dumps. Recently a revival of the industry has set in. A company purchased a number of mines and has completed a concentrating plant, which is at work on the low-grade ores. C. M. Harmon, the Mgr., is considering the advisability of putting in jigs to effect a concentration of coarser material, which also involves the addition of other concentrating machinery—trommels, etc.

The Albemarle Co. of Cochiti, promoted by J. A. Coram, is to enlarge the mill, which has a present capacity of 250 tons per day.

Silver City *Enterprise*: A. E. Dawson, Gen. Mgr. for the Santa Rita Copper & Iron Co., will start pumping from the Romero shaft next week; the machinery is upon the ground. T. Knucky will superintend the work. It is rumored that a syndicate will purchase the group of Santa Rita copper mines. The shaft is 500 feet in depth.

Bland *Herald*: The Cochiti M. Co. will put in an electric plant to generate power for the Albemarle mine.

OREGON.

Another rich strike is reported from the Bonanza mine, thirty miles west of Baker City.

Spokane *Miner*: The most valuable rock in the Bonanza, Baker City district, contains considerable tellurium. The mill process entailing too much loss, it is being shipped to the smelter.

Idaho *Statesman*: The Badger G. M. & M. Co., near Susanville, November last, bonded the Badger, McQuade, Hughes, King of the Hills, Steamboat, Great Eastern and Fraction claims. Since then the company has built a 10-stamp mill and shipped over 400 tons of ore, with average smelter returns of $150 per ton. They have also purchased the Sloane quartz claims, Bull of the Woods, Mocking Bird, Poor Man, Alta and Blue Jay. There is an 8 stamp mill in operation on this group. Four adjacent claims have been added to these.

Jacksonville *Times*: A number of claims have been located on a body of quartz near Merlin, Josephine county. The ore is said to assay from $10 to $80 per ton, and the belt is reported to be several miles long.

Baker City *Democrat*: The news of the crosscutting of a 4-foot vein of ore in the Ibex mine is received and samples of the ore showing gold are exhibited in the city. This property was recently sold to Eastern capitalists for $65,000. — At Elkhorn mountain the Standard Oil Co. have secured control of the Denny group and the Robbins-Elkhorn mine and a consolidation effected. A 7000-foot tunnel will be driven by Burleigh drills by the use of electrical power generated at the head of Pine creek.

It is thought the dredger will be at work near Huntington early in April.

Boise *Statesman*: Seven hundred feet of rails have been ordered for the Magnolia mine in Grant county, a property under bond to Seattle people.——The Pomeroy Dredging Co. is now working thirty-five men near Huntington and will employ fifteen or twenty more when running in full capacity, paying $3 per day; board $4 50 per week. Their boat is 134 feet long and 34 feet wide. They have four carloads of machinery. The company has bought ground all along Burnt river as far as Huntington.——The Connor Creek M. & M. Co. are about to reopen their mine. Timbers are being hauled in for retimbering. This mine is one of the oldest gold producers in Baker county. The 35-stamp mill will be started and will employ in mine and mill about fifty men.——The Huntington M. Co., whose placer mine is one mile below the quartz mine, will increase their force.——C. E. Gault, president of the Virtue consolidated mines, has paid $60,000 to W. Smith, Baker City, Or., for the Collateral mine, a claim near the Virtue, six miles east of Baker City. The Collateral was bonded for $75,000 due in July next, but the offer of cash payment accounts for the saving of $15,000. The company has been reorganized for $1,250,000 and the consolidated properties will be worked. The first step will be the pumping out of the old Virtue.

SOUTH DAKOTA.

The Deadwood-Terra mine and mill are again in full blast after an idleness of months since the fire in July.——A number of mines in Blacktail are ready to ship as soon as the roads permit.——Attention is being directed to the region of eruptive rocks above Central City.——The new mill at Gayville, built by the Baltimore & Deadwood M. Co., is now completed.

Five carloads of ore were shipped recently by McDonald Bros. to the D. & D smelter at Deadwood. The ore is high grade, running in the neighborhood of $35 per ton. This ore is taken from the old Cyanide ground, on which the McDonald Bros. have a lease.——May & Faust are increasing their force of miners at Garden City. The Garden City cyanide plant is closed down for the present, but will start up when the weather is settled.

UTAH.

The mines of the Niagara M. Co., at Bingham, are producing forty tons of ore daily.

Mgr. J. Long of the Mammoth and Breckenridge mines of Gold mountain, left Salt Lake recently to make preparations for erecting a mill near the mines.

Salt Lake *Tribune*: Work on the new smelting plant of the newly consolidated Bingham mines will be commenced at the earliest practicable moment. It will be the largest pyritic smelter in the world. J. W. Neill will have the management of the company's property.——A ton of auro-cyanide was received at Salt Lake last week from the cyanide plants, worth $50,000. Some of it ran up to $80 per pound.——The upraise which was begun at 200 feet in the Tesora, at Silver City, has reached the surface. The breaking down of ore commenced at once, and the marketing of it will begin soon.——Five carloads of elaterite will be shipped at once from the Raven Co.'s mines, near Price.——The Bingham tunnel is in 1250 feet in hard ground.——The retimbering of the shaft on the Blue Bird Extension at Diamond, Tintic district, has been completed, and sinking will commence at once from a depth of 120 feet.

Park *Record*: The Clarissa Gold & Copper Co., at Park City, will sink a 300-foot shaft as soon as supplies can be gotten on the ground. ——A good prospect has been struck in the Whitehead mine, northeast of the Ontario, by miners doing assessment work.

At the Queen of Sheba, at Ibapah, in the Deep Creek country, the mill recently burned by fire is being rebuilt.

Salt Lake *Tribune*: The Mercur mine has sent to Salt Lake 1310 pounds of gold dust from its cyanide plant, the value of which is estimated at nearly $25,000. This is the second consignment that has come from the enlarged plant. In a short time the management will take up the matter of starting the old pioneer plant upon the mill tailings.——The mines at Castle Gate employ 400 men in mine, tipple, coke ovens, etc. Some 1200 or 1300 tons of coal is extracted daily, of which about 1000 tons is shipped as commercial coal, while 250 sacks of crushed coal, including "slack," is run into the 104 ovens to produce over 100 tons of coke per day. This coke industry gives employment to about forty men the year round. All machinery used in operating the hoists, electric locomotive, etc., around the mine is generated in a power-house where one large engine sends out near 400 H. P. by means of four generators. The company intends putting in a modern engine and dynamo at once, which will more than double the present capacity of the plant, the two engines to run side by side. Steam is now generated in four boilers, to which three are to be added.——There are twenty-two men employed by the company at the elaterite mines in Indian canyon, and more are being added as fast as there is room to work. Teams are on the way to haul out the first shipment.

Tribune: Manganese has now made its appearance in the breast of the drifts of the Alliance mine at Park City and sensational changes are promised at any shift.

Tintic *Miner*: The Victoria M. Co., with a capital stock of 250,000 25-cent shares, has been formed to develop the Sullivan, Six-Shooter, Victoria and Victoria No. 2 claims, lying north of and in the strike of the ore bodies of the Grand Central. The principal place of business will be Provo; L. Holbrook, Pres.; J. R. Twelves, Sec. and Treas.

Salt Lake *Tribune*: The Daisy of West Dip has sent to the gold sampler a little over 200 pounds of gold dust, known to have been better than $60 a pound. The Daisy was the first on the West Dip to begin marketing auro-cyanides, although the building of its mill was antedated by the Cigale.

WASHINGTON.

Pres. Jim Hill of the Great Northern wants Spokane to build a smelter.

The North San Poil, south of Republic, in which the recent strike was made, is a 300-foot fraction between the San Poil and Ben Hur. A shaft is being sunk.

J. E. Rockfeller's mining interests at Everett and Monte Cristo have been reorganized. It is expected that a general resumption of work will begin at Monte Cristo and the smelter at Everett. The properties are now in the possession of Rockefeller, Hoyt, Gates, Carey and associates. The debts and obligations of the mine Pride of Monte Cristo amounted to $143,345; Monte Cristo, $98,947, and United Concentration Co., $169,344, a total of $421,637. Stockholders of the old companies are to pay an assessment of about $101.50 on each 1000 shares of the old stock and retain their interest in the new company.

Spokesman-Review: The owners of the Sunset claim, within a mile of Northport on the reservation, at a depth of 20 feet have a good showing of galena and copper. Sinking on the other side of the ledge and about 100 feet from the former shaft has commenced, in which there is a streak of ore 10 inches wide.

Everett *News*: Two new mines in Snohomish county will ship ore the coming summer. It is possible the Monte Cristo mines will resume their output, and the Penn Co. may be able to smelt some of its ore. The new mines are the Sunset and the Forty-five—the former in the Silver Creek and the latter in the Sultan district. The Sunset is a copper proposition.

Spokesman-Review: A galena strike has been made on the Bullion group near Flat creek, Colville reservation, in a 45-foot shaft. ——The McKinley, at Greenville, Colville reservation, carries a peculiar black ore which is reported to average $18 in gold and copper. The vein has just been crosscut in the lower tunnel.——The shaft on the Churchill is down 135 feet. A road has been completed to the mine.——The Mountain Lion mine, Republic, which is developed to a depth of 350 feet, claims to have ore averaging $35 per ton. A compressor plant is being put in.——E Spedden is taking out fine copper ore from the Single Standard, one and a half miles east of Chewelah. The ledge is 2½ feet wide on the surface.

Spokane *Miner*: Coal has been discovered in Whatcom county.

WYOMING.

Cheyenne *Tribune*: A copper strike is reported having been made on the level prairie on the east side of the Platte river, fifteen miles north of Grand Encampment. Several small test pits were sunk along the vein for a distance of over 2000 feet and copper ore found in each place.

The prairies of Wyoming are strewn with fragments of copper-stained quartz over hundreds of square miles.

FOREIGN.

AUSTRALIA.

According to the *North Queensland Herald* a sensational find of opals is reported from Winton, Queensland. Two Germans left their claim to two men named Shillington and Greenwood, who had only removed a few inches of earth when they struck a big opal band. This, when opened up, resulted in the unearthing of one of the largest blocks of opal ever discovered, and it is valued at between £7000 and £10,000.

BRITISH COLUMBIA.

According to local reports, the gold strike on Granite creek, near Alberni, on the west coast of Vancouver island, assays $6000 to the ton.

The Dorothy Morton, at Fanny bay, and the Athabasca, near Nelson, this week shipped four gold bricks valued at $17,000.

About seventy men are employed in the Queen Bess in the Slocan.

It is reported at Nakusp that the Silver Queen group, at Cariboo Creek, has been sold to an American syndicate for $200,000.

On the Jennie mine, near Fort Steele, a strike of 2 feet of clean copper ore was made last week. All ore shipments go to the Canadian Pacific smelter at Trail.

It is reported the British America Corporation will shortly commence work on the Watson group, near Elko, in East Kootenay.

Four carloads of ore from the St. Eugene mine, near Moyle, were shipped last week to the Trail smelter.

Libby *Mountain News*: February's shipments of ore from Slocan mines have brought the total shipments since January up to 6500 tons.——The Slocan Ore Purchasing Co. has been organized to build sampling works at Nelson.——Greenwood is the center of a district twenty miles square, in which are located a dozen camps, all showing considerable activity.——The Mines Development Co., which lately secured the Swansea, in the Windermere district, northeast of Golden, will spend $25,000 in development work.

Spokane *Chronicle*: Nearly 650 feet of work has been done on the Golden Crown, in Wellington camp, Boundary. Machinery is installed and a large amount of copper ore is on the dump——J. Dixon has bonded from F. Staubert the Silver Queen, on Great Northern mountain, in Lardeau, for $25,000.——E. C. Finch of Rossland has bonded for $80,000 the Mabel and Oro claims, in Central Camp, in Boundary, also, the Cornucopia, which adjoins them, for $10,000. The claims run high in copper.——Work has begun on the Main claim, in Summit camp, in the Boundary.——A contract has been let to sink a shaft 150 feet from the principal crosscut in the Iron Colt, at Rossland. The tunnel is now in about 1300 feet. The present workings are in ore all the way. When the contract is completed a depth of 520 feet will have been attained.

Spokane *Chronicle*: The Le Roi resumed shipments March 9th and by Saturday evening had sent 825 tons down to the Northport smelter. The machinery has all been repaired. It is expected that the ore output will average above 300 tons a day. The Le Roi will increase its working force as fast as the men can be used to advantage.

Ymir *Miner*: The Deer Trail, owned by F. Hazelwood of Northport, Wash., is working fourteen men and down 35 feet on the ledge and sinking. They have a 5-foot ledge with 2 feet of arsenical iron and copper pyrites carrying gold.—— The Singleheart, one mile northeast of the Relief, is owned by T. Kane. They are working one shift, running a drift on the vein.——The Relief continues to ship 120 tons per week, making it the heaviest shipper in the Kootenays outside of the Slocan or Rossland mines, the ore averaging $75 per

ton. It is learned that it is the company's intention to erect a concentrator in the near future. The mine is thirteen miles north of Erie, on the north fork of Salmon river.

Spokane *Chronicle*: The Waffet mine near Erie, B. C., is developed by a drift of 175 feet on the ledge. There are two crosscuts, one north 60 feet, 75 feet from the mouth of the tunnel, where a vein intersects, and one southerly to cut a parallel ledge and by winze sunk on the ledge 60 feet from the mouth of the tunnel, which is 50 feet deep. The ore carries values of $14 in gold and 6% in copper. In a crosscut from the bottom of the winze a body of ore has been found, the width of which has not been determined.——Arrangements are being made for the erection of a 400-ton smelter at Greenwood ——The company was organized and is headed by J. P. Graves.

CANADA.

The Regina mill, near Rat Portage, ran 242 hours in January and crushed 615 tons of ore. The yield of gold was 255 ounces, of which 225 came off the plates and 30 from the cyanide treatment. The shaft is now down 450 feet, and is to be continued On the 450-foot level a crosscut of the vein was made exposing 5 feet of quartz, some of which shows visible gold.

ONTARIO.

(Special Correspondence).—The Deloro mispickle is now being successfully treated at small expense. By free milling process 60% of the gold is saved; the concentrates are then treated by the "Sulman process" which extracts 90% of the remaining values, making a total ex raction of 96%. The tailings are roasted for arsenic. A 10-stamp mill is producing about $6000 gold per month. The Belmont mine with a 10-stamp mill is producing about $6000 per month from free-milling ore. Air compressors are being put in at each of these mines and thirty to forty stamps will be added. The "Central Ontario" mining region about 1000 miles east of Rainy river district will soon become a factor in the gold product of Canada.

Bellville, Ont., March 6th, '99.

MEXICO.

Juan Romero claims to have found a rich vein thirty-five miles east of Ensenada, Lower California, near the San Nicholas mine.

A letter recently received from the camp at Alamo, Lower California, the scene of a stampede in 1889, says that there are some very good prospects in that section, which only require development to make them producers.

Two Republics: The Corralitos M. Co. has increased the number of its employes at the Cinco de Mayo mine in the Escondida mountains. The new owners of the Dos Cabezas have added 150 miners to the force and other owners of mines in the Sierra Madre country will do likewise.

Nogales *Oasis*: Professor Dumble is experting the coal fields near Barranca. Development work is in progress. In one place a drift is run 100 feet in a coal bed 8 feet in thickness. —— Development has progressed upon the gold properties of W. S. Sturges in the Altar district, nine miles from the Gulf coast, and reduction machinery will be ordered at once.——An exploration and development company, to prospect and work mines in the Yaqui country, about La Dura, has been organized at Prietas.——The La Bufa mine near La Dura continues to improve. Last week a pack train took thirteen tons of ore into Prietas for shipment. The value of the lot was more than $4000. The property adjoining the La Bufa—the Apache, same owners—is also improving.

Industrial Notes.

—Reno, Nev., has disincorporated to reduce the tax levy.

—Japan proposes to put $9,000,000 into a Government foundry.

—This will be a great year for pumps and irrigating machinery in California.

—Drought and local stress have caused the failure of two banks at San Luis Obispo, Cal.

—Work has begun on the new sewer system of the City of Mexico, to be finished in four years.

—The San Francisco Building Trades Council favors the Pacific Ocean and International Exposition.

—A new drydock is to be built at Mare Island, Cal., large enough to accommodate the largest vessels.

—Proposals for bids for the Cedar River, Wash., water system construction are advertised for on page 298.

—A telegraph line is to be built this season by the Dominion Government between Lake Bennett and Dawson, N. W. T.

—Large docks, great machine shops and suitable naval station are to be established by the United States at Manila.

—Governor Gage has vetoed the California Assembly bill, allowing laborers in sawmills and logging camps an hour for lunch.

—The San Francisco telephone exchange heads the list in ratio to population of any city in the world, with 13,799 subscribers.

—Santa Fe trains will be running across the Tehachapi and into Stockton, Cal., by July 1st, '99, by a trackage arrangement with the S. P. Co.

—During '96-'97 Mexico exported more tobacco to Cuba than to all the rest of the world. It reached the United States as "Havana" cigars.

—The bill appropriating $500,000 in aid of the Pacific Ocean and International Exposition, to be held in San Francisco in 1901, passed the California Assembly last Monday.

—C. A. Bailey writes to *Modern Mexico* from Tejamen, Durango, Mexico: "I am the only American in this rich mining camp of over 3000 people. We ship over $4000 worth of silver every week. A railroad is to be built at once, seventy-five miles to Durango. There is a fine opportunity here for Americans with brains, with or without cash."

—Despite Speaker Reed's sidetracking of the measure in the last Congress, it is believed that the Nicaragua canal will be built, and that at the next session of Congress a preliminary appropriation will be made therefor.

—McMutrie & Stone of San Francisco have a contract to complete the California coast railroad to Santa Barbara by May 1, 1900. The northern terminal on the gap is Hueneme. About fifty miles will close the gap thence to Elwood.

—The electric power plant of the California Standard Electric Co. is reported ready for business between Mokelumne and Stockton, Cal., 42¾ miles. This line, as in the case of the Sequalmie Power Co. of Washington, uses aluminum wire.

—Various American capitalists have recently invested large sums of money in numerous Mexican industries. One of the most recent is known as "The Mexican Plantation Association," J. A. Markley, secretary. This company has purchased a large hacienda (ranch), comprising 6000 acres, in the southern part of the State of Chiapas, near the ruins of the ancient city of Palenque. It will be utilized for the cultivation of numerous plants, chiefly caucho, coffee, cacao and vanilla.

—Consul Kindrick, of Ciudad Juarez, Mexico, writes: "There is no article of common use so much required in the northern section of Mexico as the ordinary hand pump. The soil is arid and dry and free from surface springs and small streams. There is not sufficient annual rainfall to keep cisterns filled with drinking water, and almost the only source of fresh-water supply consists of wells sunk in the earth. The water is secured by hand pumps and windmills. They are necessary at every Mexican home, at all the mining camps, and on the cattle ranges. At the camps and on the ranges, windmills are used, and they are invariably of United States manufacture. There is a growing demand for windmills and hand pumps of the latest and most approved pattern. A windmill or pump is as essential to a home in northern Mexico as a cooking stove. In consideration of the fact that pumps are such an important factor in the economy of domestic establishlishments, the Mexican Government admits them free of duty.

Commercial Paragraphs.

Juan Cuyas is the representative in Mexico of the Ingersoll-Sargent Drill Co. of New York.

The Weigele Pipe Works of Denver, Colo., put in pipe lines and giants for seven hydraulic plants in Colorado in '98. They also built three Ludlum hydraulic elevators, with auxiliary sinking pumps.

The Colorado & Southern Railway, formerly the "Gulf Road," has issued an instructive pamphlet folder called "Hints to Prospectors," giving valuable data and general information on mining in Colorado.

Flint & Lomax of Denver, Colo., are completing a mine signal system. The bells and wires for shafts are so insulated as to protect them from water that so often wets everything in the shaft. A dynamo and motor, built on the same base, can be run by live steam, compressed air, water or electricity.

The Jeanesville Iron Works Co., Denver Branch, Denver, Colo., has just received a large stock of mine pumps, No. 5 and No. 9B, improved sinkers, duplex station pumps, outside packed plungers, 4 in. to 8 in. diameter plungers by 12-in. stroke; also stock of duplicate parts for repairs. They are preparing for the spring water.

B. W. Sweet, of Denver, Colo., is the patentee and builder of a stamp mill, amalgamator and concentrator, which separates the concentrates into two classes and removes the silica therefrom. A 10-stamp mill of this pattern is being erected by the Golden Queen M. Co. at Cochise, Arizona, to be run by a 28 H. P. gasoline engine.

J. E. Greenawalt and Wm. Robinson, of Denver, Colo., are patentees and promoters of an ore reduction process, electro-chemical in character, the active agent therein being chlorine. They have a fifty-ton per day mill in operation in Denver, are erecting one of similar size in the Magnolia district, Boulder county, that State, and have sold the right to the process in a mill being erected on the Golconda mine, near Sumpter, Oregon.

The Mine & Smelter Supply Co. of Denver, Colo., are building seven Argall 4-tube roasting furnaces, of fifty tons daily capacity each, for the Economic Gold Extraction Co. at Victor, Colo. They will also ship in a few days a 20x32 hoister to the Cripple Creek district for the Independence Town & Mining Co., whose properties are better known as the Hull City placers. They are also putting in Wilfley concentrating tables to handle the chlorination tailings of the reduction works of the National Gold Extraction Co. at Florence, Colo.

The Vulcan Iron Works, San Francisco, report that they are crowded with orders at the present time, of which the more important are as follows: Cross-compound Corliss engine, 17 in and 34 in. by 36 in., to go with a pumping outfit; refrigerating and ice-making plant, complete with cold storage rooms, for steamer "Australia" of the Oceanic S. S. Co. for the transportation of chilled meat from San Francisco to Honolulu; power transmitting machinery, shafting, hangers, etc., for Mare Island Navy Yard; cast-iron screw shoes, caps, etc., for steel piles and superstructure for Government wharves at Pago Pago; machinery and miscellaneous iron work for "Chandler" coal bunkers, San Francisco; iron stairs for Hall of Justice Buildings, San Francisco; miscellaneous stamp batteries, rock breakers and other mining machinery; pair kettles, 10 feet diameter, fitted with steam coils, for Mexico; structural iron work for Bishop Museum, Honolulu.

The Denver Engineering Works Co. have just finished an 80-stamp mill for the Liberty Bell G. M. Co. of Telluride, Colo. They have also shipped thirty electric hoists of 5 to 30 H. P. each for Cripple Creek district. They have recently shipped three boilers and six electric hoists for Old Mexico, which makes twenty such hoists they have sent to that country. The same company are building six sets 16x36 Denver crushing rolls for the Economic Gold Extraction Co. of Cripple Creek. They are also making water jackets for the Globe smelter of Denver, the Colorado of Pueblo and the Bimetallic of Leadville, Colo.

The Lead Smelters' Combine.

During the week was received an advance copy of the agreement between the creators of the combination that has attracted so much recent interest, and which is styled "The American Smelting & Refining Company." The document goes into the details of the deal, and is herewith presented in full. The contract reads:

Agreement, dated March 7th, 1899, between the subscribers, severally, of the one part, and the Moore & Schley and Lewisohn Brothers of New York City, partnerships, and Henry H. Rogers of the same place, jointly and severally, hereinafter called the managers, of the other part, witnesseth as follows:

Each subscriber hereby agrees to take and pay for, at the price and in the manner hereinafter stated, the number of shares written opposite his signature hereto, or such smaller number as the managers may allot, of the full paid preferred stock, and seven-tenths of the same number of shares of the full paid common stock, of a corporation to be organized, capitalized and vested with properties, substantially, as hereinafter stated.

The price is to be $1000 in cash for each 17 shares, that is to say, 10 shares of preferred and 7 shares of common, of such stock, and is to be paid to such Trust Company as the managers may select or substitute to act hereunder, hereinafter called the Trust Company, within five days after notice calling for such payment shall be delivered or mailed to such subscriber by the managers, or any one of them, or by the said Trust Company in their behalf. If stock certificates are not then ready for delivery, the Trust Company will issue and deliver negotiable receipts, redeemable in the stocks when issued, or by return within a specified reasonable time, if the plan should be abandoned, of all payments.

The corporation which it is proposed to form with the name "American Smelting and Refining Company," or a similar name, will have appropriate powers for mining, smelting, refining and dealing in all kinds of ores, and such other powers as may be deemed convenient, and will have an authorized capital of $65,000,000, divided into 650,000 shares, of the par value of $100 each; of which stock $32,500,000 in par value is to be preferred stock, entitled, in preference to the common, to cumulative dividends of 7% yearly, and on distribution of assets to payment of its par value and the amount of such cumulative dividends then unpaid, but to no other dividend or payment, and the remainder, $32,500,000, in par value, is to be common stock.

By the issue of $27,000,000 par value of its preferred stock, and an equal amount of its common stock, the corporation will acquire $7,500,000 in cash for working capital and for other corporate purposes, and the stocks or lands, plants, properties and good wills under contract of the hereinafter named concerns in the smelting and refining business, and such other like properties, if any, as the managers may desire and be able to include, to wit: United Smelting and Refining Company; Omaha & Grant Smelting Company; Pueblo Smelting and Refining Company; Colorado Smelting Company; Hanauer Smelting Works; Pennsylvania Lead Company; Pennsylvania Smelting Company; Globe Smelting and Refining Company; Bi-Metallic Smelting Company; Chicago & Aurora Smelting Company; Germania Lead Works (or in lieu thereof all the stock representing same); and also a majority of all the stock of the Consolidated Kansas City Smelting and Refining Company, provision being made for the acquisition of the remainder of such stock from the stock to be issued by the corporation as aforesaid.

It being understood as follows:

1. That the Omaha & Grant property will be taken subject to a mortgage securing 6% bonds for the principal sum of $1,333,000, payable March 1st, 1911; and that the Kansas City Smelting and Refining Company's property is subject to a mortgage securing 6% bonds for $1,000,000, maturing May 1st, 1900.

2. That, if the managers deem it necessary or advantageous, any of the said plants, properties or stocks may be omitted from the transfer and conveyance to the corporation, the consideration therefor in such case being correspondingly reduced, or the aforesaid cash payment for working capital and other corporate purposes being correspondingly increased; and also that other plants, properties or stocks of like character may be included in such transfer and conveyance, in which case the aforesaid consideration may be increased, if the corporation shall so agree.

3. That this agreement shall not bind any subscriber until the full amount of preferred stock which shall be issued as hereinbefore recited, and the accompanying amount of common stock, shall be taken on or before May 1st, 1899, hereunder or by other agreements of purchase, but in that event shall be fully obligatory upon all subscribers.

4. That the subscribers intend their agreements herein, subject as aforesaid, to be relied upon by the managers in carrying out the plans hereinbefore referred to, and in providing the stock agreed to be taken, and that any action in that direction on the part of the managers shall constitute an acceptance hereof without notice to the subscribers, but no obligation to carry out said plans is hereby imposed upon the managers, who shall not be liable under any of the provisions of this agreement or in or for any matter therewith connected, it being understood that if the plans aforesaid are not carried out the subscribers shall be entitled only to the return of their payments and to be discharged from all obligations hereunder.

5. That the managers, or any of them, may become subscribers hereto in the same manner, and with like effect, as other subscribers.

6. That nothing herein contained or otherwise shall constitute the subscribers partners or make any subscriber liable to contribute more than the amount of his subscription, and that this agreement shall bind and inure to the benefit of the parties hereto, their personal representatives and assigns.

7. That this agreement may be executed and signed in separate writings, with the same effect as though all signatures were on one.

Personal.

C. L. & H. F. Berry have returned to the Klondike.

R. R Hedley is Mgr. Hall mines smelter at Nelson, B. C.

Gill S. Peyton has returned to Salt Lake City, Utah, from Milford.

J. W. Evans has been appointed Mgr. Four Aces mine, at Tintic, Utah.

Jas. Cusin, Lead, South Dakota, is that State's new mining inspector.

Nicholas Treweek of Salt Lake City, Utah, has gone East on mining business.

Ben Stanley Revett of Breckenridge, Colo, has returned from Boston.

Chas. Brockington is now local manager of the Orleans mine, Grass Valley, Cal.

Ex Senator S. M. White has been appointed a regent of the California State University.

Ross E Browne is still in London, and will probably visit Mexico before returning to San Francisco.

Capt. Thos. Mein has returned to San Francisco from a visit to the grant, Mariposa Co, Cal.

J. T. McConnell, Mgr. of the Raven M. Co., has left Salt Lake City, Utah, for Chicago and New York.

L. S. McLure of San Diego, Cal., is at Neihart, Montana, looking at prospects in the Little Belt mountains.

H. A. Cohen, formerly Mgr. for Capt. De Lamar, will visit the Marguerite group of mines near Milford, Utah.

L. Cummings of San Francisco is at Selma, Or., putting in a MacArthur-Forrest cyanide plant for the Requa M. Co.

E. N. Lindsay of San Francisco is in Calaveras Co., Cal., looking after the affairs of the Petticoat mine at Railroad Flat.

J. B. Adams, who is interested in copper properties in Wyoming, has returned to Denver, Colo., from the Atlantic coast.

The late Prof. Cumming Sherry, Sr., is credited with having made the first discovery of copper in the Lake Superior region.

Jas. W. Abbott, a California mining engineer for some time sojourning at Grant's Pass, Or., has gone to Lake City, Colo.

Frank S. Robbins, formerly with the Elkhorn Con. Co., Ltd., of Leadville, Colo., is now with the Brooklyn mine, Phœnix, B. C.

J. Harrowen of the Risdon Iron Works, San Francisco, Cal., is at Virginia City, Nev., in connection with the pumping work in the C. & C. shaft.

T. A. Rickard of Denver, State Geologist of Colorado, has been appointed consulting engineer of the Anchor-Moon property at Cripple Creek, Colo.

Hennen Jennings has returned to San Francisco, Cal., after an inspection of the mining properties on the Mariposa estate, Mariposa Co., Cal.

W. T. Little, of Prescott, Arizona, is in San Francisco buying machinery to replace that recently destroyed by the fire at the mine at Big Bug, Arizona.

R. J. Cory of the E. P. Allis Co. of Milwaukee is at Salt Lake City, Utah, in the interest of his company, which is equipping the Highland Boy with machinery.

M. S. Clarke, formerly Supt. Golden Province Co., Quesnelle, B. C., says that the Cariboo country will have a busy summer, and several new dredges will be built.

W. C. Ralston has returned to San Francisco from New York City. He is credited with intention to put a 100-stamp mill on the Melones mine in Calaveras Co., Cal.

Geo. Mitchell, formerly Supt. United Verde mine, at Jerome, Ariz., will go to Sonora, Mexico, to develop mines forty miles south of the international boundary.

Jno. Q. McDonald has just completed an 80-ton cyanide plant for the Rose mine near Victor, Cal., and left this week to take charge of a cyanide plant at Florence, Colorado.

W. L. Brown is in San Francisco from Crescent City, Cal., to get new machinery for his black sand deposit at the former place, with a view to saving the platinum as well as the gold.

Capt. Thos Couch of Montana and California is in San Francisco. Of big copper properties he says Calumet & Hecla has ore enough in sight at the present output rate to last thirty years.

L. Bauer, a Freiburg mining engineer, is in San Francisco en route to Corea to report on some proposed German mining investments therein. He contemplates two weeks observation of California mining methods.

Geo. E Truax, the Denver, Colo., ore car manufacturer, arrived in San Francisco from that city this week. John T. Plummer is in charge of the Denver branch of the Truax Ore Car Mfg. Co. Mr. Truax will make his home in California.

W J. Adams left yesterday, the 17th, for Alaska, where he will superintend the operations of the Latuya Bay Gold Placer Co., about 200 miles north of Juneau, about half way between that point and Yakitat. He returns next October.

On his 76th birthday was sent to Professor Jos. Le Conte of the University of California several large nuggets of South African gold from seven old graduates of the University, now prominent in gold mining in the Transvaal, viz., Webb, Hoefer, Garthwaite, Robertson, Samson, Hay, Roberts.

W. H. Blaisdell, of Yuma, Arizona, contemplates pumping water from the Colorado river to the King of Arizona mine, a distance of forty miles. Mr. Blaisdell supplied the old Paymaster mine in San Diego county, near Glamis, with water from the Colorado, a distance of seventeen miles, and more recently the Cargo Muchacho mine was similarly supplied, a distance of twelve miles.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey, Strong & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING MARCH 7, 1899.

620,821.—HOSE COUPLING—Abbey & Phillps. Redlands, Cal.

620,731 —SEPARATOR AND CLEANER—D. Best, San Leandro, Cal.

620,732.—HARVESTER FINGERBAR—D. Best, San Leandro, Cal.

620,637 —WRAPPING MACHINE—H. Bohls. S. F.

620,735.—TRACTION ENGINE—G. Cashmore, Oakland, Cal.

620,696.—CONTINUOUS RAIL—E. V. Chamberlin, San Diego Cal.

620 739.—CABLE SPLICE—P. T. Cristensen, S. F.

620,699.—VOTING MACHINE—H. A. Clifford, S. F.

620,761 —DOOR CHECK—H H. Fassett, S F.

620,767.—VOTING MACHINE—J. A. Gray, Adin, Cal

620,707.—LOCOMOTIVE ASHPAN—T. W. Heintzelman, Sacramento, Cal.

620 709.—GRATE—E C. Horst, S. F.

620 653 —CAN-HEADING MACHINE—R. D. Hume, Gold Beach, Or.

620 873 —GLOVE STRETCHER—L. Isaacs, Los Angeles, Cal

620,657.—WRENCH—J. G. Kernek, Stockton, Cal.

620 849.—HOE—C. E. Long, Pomeroy, Wash.

620,795.—FRUIT DRIER—W. Mitcham, Oakville, Or.

620,798.—FAUCET BUSHING, ETC. — R. Piotrowski, S. F.

620,801.—GRAVITY HOIST — A. C. Pratt, Carson, Nev.

620,814.—SHAFT COUPLING—C. Warren, Wolf, Cal

620,624.—MEASURING TOOL—C. R. Weymouth, Alameda, Cal.

NOTE.—Plain and Certified Copies of U. S. and Foreign patents obtained by Dewey, Strong&Co., by mail or telegraphic order. American and Foreign patents secured, and general patent business transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

INTERCHANGEABLE COAL AND GAS GRATES.—E. C. Horst, San Francisco, Cal. No. 620,709. Dated March 7, 1899. This invention relates to an interchangeable apparatus which is designed for use in connection with fireplaces and grates, and the object is to enable the user to employ a device for burning gas when it is desired to use but little fire and in moderate weather, or to move this device entirely out of the way and expose the ordinary grate for wood or coal which may be used for a larger fire. The grate comprises the usual basket for coal or other similar fuel and in connection with this is the device for burning gas, such as a gas log or the deflector, with means for placing it in position for use, or removing it, and a counterbalance, together with extensible, telescopic or connecting pipes by which the gas is brought to the distributer when in use. When not in use the distributer is moved upwardly into a chamber or receptacle where it is entirely concealed and out of the way and the grate for burning the ordinary fuel is exposed. By also making the support for the pulleys of the counterweights movable, it is easy to withdraw the whole apparatus downward from its concealing chamber for any inspection or repairs necessary.

VOTING MACHINE.—Joseph A. Gray, Adin, Cal. No. 620,767. Dated March 7, 1899. This invention relates to a machine which is especially designed to enable the voter to indicate the candidate or candidates for whom he desires to vote upon a ticket having the names of the candidates imprinted thereon, and at the same time to register his vote or votes by means of an apparatus which marks the ticket and at the same time registers the vote. The operation of the mechanism is carried out by means of a push bar having a head projecting through the front, a tablet for the reception of the name of the candidate, a punch carried by the push bar and a pawl and ratchet registering mechanism actuated by the movement of the push bar and advanced one number by each advance of the bar. In the operation of voting the voter first stamps or marks his vote by means of these push-bar devices, of which there is one for each candidate, and the operation of marking also registers a vote for that particular candidate. When the ticket has thus been fully prepared, it is folded and deposited in the ballot-box in the usual manner; and as each ticket has been punched, it has necessarily added one vote upon the register to those recorded for the particular candidates. The apparatus thus forms a mechanical check for the tickets, while the ticket is a check upon the register.

HARVESTER, GRAIN SEPARATOR AND CLEANER ATTACHMENT. — Daniel Best. San Leandro, Cal. No. 620,731. Dated March 7, 1899. This invention relates to improvements in grain separating and cleaning machines especially designed to be applied to separators and cleaners which form a part of combined harvesters such as were adapted to travel over the field, cut and thrash the straw, separate the grain and afterwards clean separated grain and place it in sacks. It consists essentially of an endless traveling open slat belt, drums over which the upper part of the belt passes in a plurality of inclined sections, the intermediate portions forming approximately vertical connections between the upper end of each inclined portion and the lower portion of the following one. Pickers are stationed above the inclined sections of the belt and rotatable in opposite directions so as to loosen up and separate the straw and forcibly deliver it upon the inclined sections. A blast apparatus is fitted to discharge through the belt and an inclined floor beneath each section prevents the straw from passing through and becoming entangled with the belt. An inclined return board extends beneath the entire lower portion. A longitudinally oscillating shoe is adapted to receive the grain, including separate screens at each end and an intermediate close floor with oppositely inclined return boards beneath the ends of the shoe, with separate conveyors to receive the grain from the boards and a blast apparatus for each person.

SPLICE FOR OLD WIRE CABLES.—P. T. Christensen, San Francisco, Cal., assignor to the Washburn & Moen Mfg. Co. of Worcester, Mass. No. 620,739. Dated March 7, 1899. The object of this invention is to provide a splice which can be employed for repairing old and worn-out cables, but it is not suitable for uniting new cables nor is there any splice employed for uniting new cables which is suitable for this work. The splice consists of the opposing sections of the cable abutting together, each having projecting strands of different lengths and composed of a plurality of wires untwisted and divided into groups, the groups of each section of rope or cable alternately laid upon each other from opposite directions and occupying the grooves or channels previously occupied by the undivided strands and having their ends tucked under the strands and secured.

FAUCET BUSHING AND STOPPER.—R. Piotrowski, San Francisco, Cal. No. 620,798. Dated March 7, 1899. This invention comprises a permanent bushing fixed in the draw-off opening of a cask or other receptacle for beer or other effervescent liquid, a cage projecting into the cask from the inner end of the bushing and a closing stopper movable within the cage adapted to close the inner end of the bushing by the pressure from the inside. When it is to be opened, it is forced inwardly by suitable operating means, the stopper being pushed into the cage which allows a free passage for the liquid. The shape of the interior wall of the bushing is such that when the stopper is drawn forward it forms a perfectly tight joint therewith; when pushed back it fits snugly within the cage and is thus held in place and prevented from again moving forward to stop the opening. A loop or ring upon the outer end of the stopper may be engaged by a hook or suitable implement to either force the stopper back or draw it forward to close the bushing. The stopper can be pulled forward into the bushing when the interior of the cask is to be pitched, as it is termed, and the pitch flowing over the inner end of the stopper is prevented from entering and clogging the bushing. When the stopper is forced backward into the cage it breaks the pitch which is brittle and thus leaves a clear passage for the liquid when the faucet has been introduced.

HARVESTER GUARD FINGER BAR.—Daniel Best, San Leandro, Cal. No. 620,732. Dated March 7, 1899. The object of this invention is to provide for the making of the guards and fingers through which the reciprocating sickle moves in cutting the grain, in independent sets or sections, and in so constructing the guard as to prevent a loss of grain over the front when the machine is depressed at an angle to cut low grain. It comprises a plate secured to the upper surface of the bar or support at the front of the machine having integral fingers projecting horizontally in the plane of and from the front edge of said plate, said fingers provided with grooves or channels for the cutter sections and cutter bar having an upwardly projecting rib along the front edge with a lip projecting forward of the rib to overhang the cutter bar.

A Suggestion From Colorado.

TO THE EDITOR:—We note in your issue of March 4th, under "Concentrates," the following:

A question of some importance in California is how may the large piles of roasting sulphides (tailings of chlorination works), containing values in gold of $5 per ton and upward, be successfully treated at a profit?

The various chlorination mills operating in and around the Cripple Creek district, in this State, are daily handling about 500 tons of ore, the tailings of which are being concentrated by means of the Wilfley concentrating tables and are being made, commercially, a success, although the tailings, as delivered to the concentrators, contain from $1.10 to $1.40 per ton. Not knowing the exact conditions surrounding the tailings in California, we do not know if the same treatment can be applied, but simply offer you the above as a suggestion.

THE MINE & SMELTER SUPPLY CO.

Denver, Colo., March 11th, '99.

Catalogues Received.

"*Pumping and Hydraulic Machinery.*" W. T. Garratt & Co., a quarto, 106 pages, elaborate and complete; illustrated description of pumps and water-supplying devices for every requirement, of present interest to many; hand and power pumps, hydraulic rams, centrifugal pumps, and, in general, everything applying to the practical supplying of water; finely illustrated and described in detail. The book is unusually handsome throughout and of timely value. A copy will be sent to any address on request by W. T. Garratt & Co., Fremont & Natoma Sts., San Francisco, Cal.

Books Received.

"*Examination of Water (Chemical and Bacteriological),*" 12mo., pp. 1351. W. P. Mason. From a sanitary and analytical standpoint; with numerous tests, formulæ and examples. Jno. Wiley & Sons, N. Y., $1.25.

NOTICE TO CONTRACTORS.

NOTICE TO CONTRACTORS.—Sealed proposals will be received on or before one (1) o'clock P. M., April 12th, 1899, for the construction and completion of certain additions to the existing water works owned and controlled by the City of Seattle, Washington. The said additions include a gravity water supply from Cedar river, reservoirs and portions of an auxiliary high service system in the city. The contract will be let in four (4) separate subdivisions, and will embrace the following general terms of construction:

In Subdivision One (1):

Head works on Cedar river, consisting of Diverting Weir, Intake Canal (400 feet long), Settling Basin, Gate House, Dwelling House and Stable.

Pressure Pipe from Head works to High Service Reservoir in City Park, said pipe being 42 inches in diameter and 28.4 miles in length; of which 6.4 miles are to be riveted steel and 22 miles to be wooden stave pipe banded with steel bands ⅝ inch in diameter; wooden stave and steel pipe between High and Low Service Reservoirs, 30 inches in diameter, about one mile in length.

Wooden Stave Pipe 24 and 30 inches in diameter respectively, about 4400 lineal feet, as waste pipe from High Service Reservoir to Lake Union.

Change of Cedar River channel, 65,000 cubic yards excavation.

Improvements at Swan Lake, consisting of clearing land, construction of dam at outlet, Intake and pipe connection with said Lake.

In Subdivision Two (2):

High Service Reservoir and Gate House in City Park (capacity of said reservoir being about 16 million gallons); Low Service Reservoir with Gate House and Pumping Plant in Nagle Addition (capacity of reservoir about 20 millions gallons; capacity of pumping plant 3 millions gallons in 24 hours).

In Subdivision Three (3):

Stand Pipe on Queen Anne Hill, 30 feet diameter by 60 feet high, incased in "Ransome Concrete."

Force main from Low Service Reservoir to Stand Pipe on Queen Anne Hill, also to Renton Hill said mains consisting of 13,200 lineal feet of 12-inch and 2690 lineal feet of 16-inch Kalamein pipe.

In Subdivision Four (4):

Pipe line from the Low Service Reservoir to the present distributing system, consisting of 3580 lineal feet 30-inch riveted steel and 1240 lineal feet 30 inch cast iron pipe, also 250 lineal feet 24 inch riveted steel pipe, for connecting said reservoir with Tenth Avenue Sewer.

Separate bids will be received and separate contracts will be let for each of said subdivisions. The work will be let to the lowest bidders therefor. The total cost of said work is limited to $1 250,00. The contract to be entered into will provide that payment shall be made for this work only by warrants upon the "Cedar River Water Supply Fund of Seattle," as created and established by Ordinance No. 3990 as amended by Ordinance No 5258, and the contractor shall have no claim against the city except as therein provided. Said ordinance provides that such warrants shall have interest coupons attached, and shall bear interest at the rate of five (5) per cent per annum, payable semi-annually on the first days of January and July of each year; and the city of Seattle absolutely and irrevocably pledges, out of the revenues from its water works system now owned, or which may hereafter be owned, operated or controlled by it, a sum not less than one hundred thousand ($100,000) per annum, to pay the principal and interest of said warrants as aforesaid, when the same shall become due.

In addition to the warrants which will be issued in payment for the construction of said additions, the contractor will also be required to purchase at par any and all warrants which shall be drawn on said fund by the city in such amounts as shall be required to pay for any real estate, rights, easements or privileges necessary for the prosecution of the work of construction and the perpetual control by said city of the additions to the water works herein specified, whether obtained by purchase, agreement or condemnation proceedings, and also such warrants as shall be drawn upon said fund by the city in payment of engineering and other expenses necessarily incurred in connection with said additions; provided, that the total amount of the warrants thus required to be purchased by the contractor shall in no case exceed the sum of sixty thousand ($60,000) dollars, and shall be distributed as follows, to wit:

Against subdivision No. 1, the sum of forty-five thousand ($45,000) dollars; against subdivision No. 2, twelve thousand ($12,000) dollars; against subdivision No. 3, two thousand ($2,000) dollars; against subdivision No. 4, one thousand ($1,000) dollars.

Each bid must be accompanied by a certified check, payable to the order of the City Comptroller, for a sum not less than five (5) per cent of the amount of the bid, and no bid will be considered unless accompanied by such check.

The successful bidder will be required to enter into a contract and furnish satisfactory bond for the amount required by the City Charter and the laws of the State of Washington, within ten days after being notified of the award of the contract to him; failing so to do, the said check and the amount thereof shall be forfeited to the city. No person is eligible as a bidder who has within two years prior to the letting of said contract made default in payment of any just claim for any work or labor performed, or any skill or material furnished pursuant to any such contract as herein advertised, or who within said two years failed to complete any such contracts.

Special attention is called to article xxiii. of the City Charter, as now in force, relating to "hours of labor."

All bids must be made in accordance and compliance with the plans and specifications now on file in the office of the Secretary of the Board of Public Works, and in compliance with Ordinance No. 3990 as amended by Ordinance No. 5258.

The City of Seattle reserves the right to reject any and all bids.

Proposals must be endorsed on envelope "Bid for Constructing Subdivision No. —— of Certain Additions to the Water Works of the City of Seattle"

By order of the Board of Public Works.

FRANK OLESON, Secretary.

Date of first publication March 11th, 1899.

HEALD'S

BUSINESS COLLEGE.

24 Post Street, - - - San Francisco.

MINING AND CIVIL ENGINEERING DEPARTMENT: Mathematics, Draughting, Strength of Material, Chemistry, Assaying, Blow-Pipe Analysis, Geology, Mineralogy, Surveying, etc., under the direction of Prof. O. H. Packer, an engineer of national reputation.

ELECTRICAL DEPARTMENT: Theory and Practice; Construction.

BUSINESS: Bookkeeping, Shorthand, Typing, Modern Languages, etc.

Twenty teachers; individual instruction; can enter at any time; Catalogue and Journal free.

MINING ENGINEER WANTS POSITION. Thorough chemist and assayer; practical experience of stamp milling, chlorination and cyanide processes. Three years' experience examining and reporting on mines. Familiar with Mother Lode. Any capacity; moderate salary. Address "B. L." this office.

A MINING DETECTIVE —"Confidential," operating in California, Arizona and Colorado. I am prepared to investigate as to habits of employes on duty (also off duty) in mine and mill, particularly the art of stealing gold specimens, amalgam, ores, etc., from mining companies. Best of references. Reasonable terms. Address "Confidential," M. & S. P. Office, San Francisco, Cal.

WANTED—Position by a Mining Engineer Assayer and U. S. Mineral Surveyor.

Speaks Spanish fluently. Best of references. Address P. C., this office.

WANTED—SITUATION BY A PRACTICAL MILLMAN AND ASSAYER.

Would go anywhere Best of reference. Address F. B., care of Mining and Scientific Press.

WANTED — POSITION BY A CHEMIST, ASSAYER and MINING ENGINEER.

Cyanide a specialty. Speaks Spanish. First-class references. Address Box 28, this office.

WANTED.

Capital to Handle Extensive Gold Mines.

JAMES ARTHUR, Cornucopia, Oregon.

Wanted to Bond a Gold Mine

IN CALIFORNIA OR ARIZONA, on which parties will do development work.

Address P, 347 Wilcox Building, Los Angeles, Cal.

Have Purchasers for Good Copper and Gold Mines

IN THIS STATE, ARIZONA AND MEXICO. Reliable reports required and options later, if approved of. RUSSELL & POOLEY, 349 Wilcox Building, Los Angeles, Cal.

..CRIPPLE : CREEK..

FOR SALE—CYANIDE PLANT,

100 tons daily capacity; in first-class condition to handle Cripple Creek ores.

Plant in full running order, with all latest improvements. Address JOHN S. MACBETH, Equitable Building, Denver, Colorado.

DIAMOND DRILL

FOR SALE,

OR CAN BE HIRED, TOGETHER WITH EXPERT TO OPERATE IT.

Apply to J. A. MURRAY, care of Risdon Iron Works, San Francisco.

THE GOLD and SILVER EXTRACTION COMPANY, OF AMERICA, LTD.

CAPITAL, - $550,000.

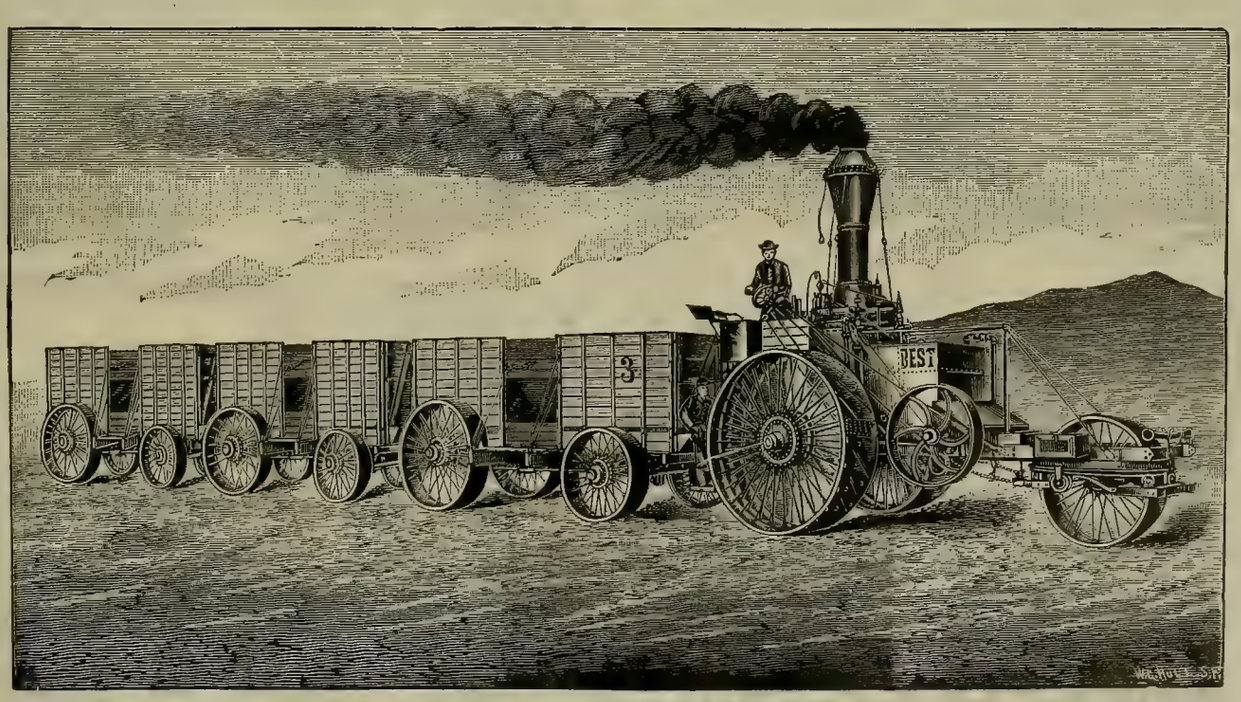
222 MARKET ST., SAN FRANCISCO, CAL.

A REVOLUTION IN FREIGHTING.



THESE WAGONS ARE ESPECIALLY ADAPTED FOR STEAM FREIGHTING; CAPACITY OF TRAIN 50 TONS.

"The Daniel Best" 50-Horse Power Traction Engine.

The most powerful and only Successful and Practicable Road Engine in the World. Over sixty of them in use in this State, and they are being Successfully and Profitably Employed in Hauling Log Lumber, Ore, Salt, Borax and other kinds of freight

The work is being done **FIFTY PER CENT** Cheaper than it is possible to do with Animal Power. They can be operated over any ordinary road where it is practicable to use mules or horses, doing the same work. They can ascend or descend grades as much as 20 to 30 inches to the rod, hauling their loads of 35 to 40 tons, depending upon the condition of the roads; loads may be increased to even greater amount on moderately level roads.

Send for descriptive Circulars and price List of Wagons and Engine. We solicit correspondence. No trouble to answer questions.

Estimates made for complete Steam Freighting Outfits. Address

Operator taking courses or horizontal angles with BRUNTON'S PAT. POCKET MINE TRANSIT.
If you wished to find the angle between two points below the horizontal with a sighting compass or an ordinary transit, you would first have to set up your tripod or staff and then level up your instrument. All this takes time.
If you only wanted to get the angle within a degree or so, you could take a BRUNTON TRANSIT, and holding it in the position shown, take your readings in less time than you can place any other instrument. Send for descriptive catalogue B to

No. 044 BUTTON BALANCE. Sensibility 1-100 milligramme. If you are in the market for the very best balance obtainable at a moderate price, write us for particulars about the No. 044. You will be surprised to find how cheaply it can be purchased for cash. While we cannot recommend this balance for fine gold work, a great many assayers are using it for such successfully. Send for illustrated catalogue A, for complete description and prices, to

PATENTS

DEWEY, STRONG & CO'S PATENT AGENCY.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American reports, with full copies of U. S. Patents since 1872. All worthy inventions patented through DEWEY, STRONG & CO.'s Patent Agency will have the benefit of a description in the *Mining and Scientific Press.* We transact every branch of patent business, and obtain patents in all countries which grant protection to inventors. The large majority of U. S. and foreign patents issued to inventors on the Pacific Coast have been obtained through our agency. We can give the best and *most reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and circulars free.

P&B BUILDING PAPER

The walls of a house are built for protection. If the sun and weather open up the sheathing, the rain or the air will get in and cause discomfort and doctor's bills. To prevent this the architect or builder uses building paper. There are many kinds, but only two classes—the poor and the good. P & B PAPER is good—the best. It is very strong, odorless, waterproof and airproof, and will not rot. Ask your dealer for samples, or write us for them. We are the makers.

Dewey, Strong & Co., Patent Agents,
330 Market Street, San Francisco, Cal.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY, STRONG & CO., Patent Agents, 330 Market St., San Francisco, Cal.

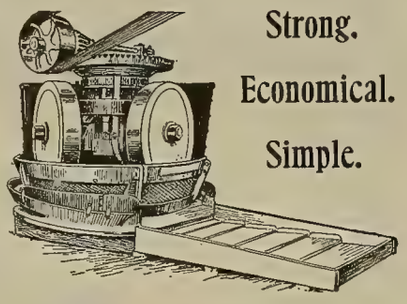
"Hercules" Ore Crushers;
"Challenge" Ore Feeders;
"Triumph" Ore Concentrators;
"Hendy-Norbom" Ore Concentrators;
"Triple Discharge" Two Stamp Mills;
Hydraulic Mining Machinery;
Hoisting, Pumping and Irrigating Plants;
Boilers, Engines and Pumps;
Tangential Impact Water Wheels.

THE BRYAN ROLLER QUARTZ MILL.

We are the sole manufacturers of this Mill. A test made by the Bullion-Beck Co. of Eureka, Utah, with this and the Huntington Mill proved conclusively every claim we made for the Bryan Mill, viz: that the Bryan would crush more ore with less repairs, less power and less slimes than any Mill made. Result—they are now operating three of the five-foot Bryan Mills and find them superior and more satisfactory than any Mill they ever used. L. C. Trent & Co., who had formerly sold the Huntington Mill, immediately manufactured a Mill infringing our patent. Suit brought in the U. S. Court resulted in a verdict in our favor, and we shall prosecute to the full extent of the law any infringement of any character whatsoever in the MAKING, USING or SELLING of the same. : : : : : : : : : : : :



Strong.
Economical.
Simple.

MANUFACTURED BY

The BRYAN MILL is constructed on the principle of the Chili Mill, except it has three rollers arranged to run in a continuous discharging pan. It crushes either gold or silver ores. It consists of an annular cast-iron mortar with fixed steel dies arranged in the path of its three crushing rollers. Power is applied direct from a pulley through a bevel gear and pinion secured to stationary center post. We present a few of many advantages it possesses over any other Mill: Larger screen capacity and free discharge. Amalgamates a larger percentage of gold. Quickly and cheaply erected; with regular feed and proper flow of water requires little attention. Crushes hard or soft ore with smaller amount of power per ton and less wear and tear of machinery. : : : :

Assessment Notices.

EUREKA CONSOLIDATED DRIFT MINING COMpany.—Location of principal place of business, San Francisco, California; location of works, Forest Hill Divide, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 9th day of March, 1899, an assessment (No. 17) of one-half of one cent per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 1209 Claus Spreckels building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 11th day of April, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 28th day of April, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

J. J. CRAWFORD, Secretary.

Office—1209 Claus Spreckels building, San Francisco, California.

BEST & BELCHER MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Virginia District, Storey County, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the seventh (7th) day of March, 1899, an assessment (No. 66) of ten (10c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, Room 33 Nevada Block, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the tenth (10th) day of April, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the second (2nd) day of May, 1899, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

M. JAFFE, Secretary.

Office—Room 33 Nevada Block, No. 309 Montgomery street, San Francisco, California.

MARINA MARSICANO GOLD MINING COMpany.—Location of principal place of business, San Francisco, California; location of works, Sunny Hill, Shasta County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 11th day of March, 1899, an assessment (No. 18) of 5 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, 217 Sacramento street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 17th day of April, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 8th day of May, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CHARLES BOVONE, Secretary.

Office—217 Sacramento street, San Francisco, California.

And in accordance with law, and an order from the Board of Directors, made on the 10th day of January, 1899, so many shares of each parcel of such stock as may be necessary will be sold at public auction at the office of the company, No. 310 Pine street, Rooms 15 and 17, San Francisco, California, on TUESDAY, the 21st day of March, 1899, at the hour of 1 o clock P. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

J. W. PEW, Secretary.

Office—No. 310 Pine street, Rooms 15 and 17, San Francisco, California.

THE CALIFORNIA DEBRIS COMMISSION, having received applications to mine by the hydraulic process from D. M. Butterfield, in the Santa Cruz Placer Mine, near Quincy, Plumas Co., to deposit tailings in a worked-out pit; from the Horg Fat Company, in the Doherty Mine, at Howland Flat, Sierra Co., to deposit tailings in the East Branch of Slate Creek; from Sam Ahtye, in the Spanish Flat Mine, near La Porte, Plumas Co., to deposit tailings in worked-out pits; and from J. D. Wetmore and Martin Tufford, in the Dry Creek Mine, near Brownsville, Yuba Co., to deposit tailings in Dry Creek, gives notice that a meeting will be held at Room 59, Flood Building, San Francisco, Cal., on March 20, 1899, at 1:30 P. M.

The State Ore Sampling Co.

DENVER, COLO.

We buy Gold, Silver, Lead, Copper, Bismuth, Uranium, Wolfram, Cobalt and Antimony Ores. With modern mills and machinery our facilities for sampling ores are the best.

Our long experience in the market enables us to obtain the highest prices for all marketable ores. Write for our "Reference Book." Send analysis of your ore for prices and information.

BAILY & MONNIG, Managers.

Skeleton Mining Report.

NEEDED BY EVERY MINING MAN.

FIFTY CENTS POSTPAID.

Mining and Scientific Press, 330 Market St., S. F.

Mining and Metallurgy.

The latest and best books can be had from the Book Department of the MINING AND SCIENTIFIC PRESS at best prices. ALL BOOKS SENT POSTPAID. Following is a partial list:

ASSAYING:—PART I—GOLD AND SILVER ORES.
Third edition: Rewritten and Improved by the Author, C. H. Aaron; 130 pages, illustrated....$1

ASSAYING:—PARTS II & III—GOLD AND SILVER BULLION, LEAD, COPPER, TIN, ETC.
Latest edition: 161 pages, illustrated, cloth. Much of the original text replaced by new matter....$1 75

ROASTING OF GOLD AND SILVER ORES AND THE EXTRACTION OF THEIR RESPECTIVE METALS WITHOUT QUICKSILVER:
Second edition; Guido Kustel, M. E.; 156 pages, with illustrations of furnaces, supplements and working apparatus....$3

PRACTICAL TREATISE ON HYDRAULIC MINING:
By Aug. J. Bowie, Jr. On the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on heavy grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc....$5

PRACTICAL HYDRAULICS:
A book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers and Irrigators. By P. M. Randall. Contains useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulæ, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules and tables are prepared. Is specially applicable to the Pacific Coast....$2

MODERN COPPER SMELTING:
E. Dyer Peters, Jr. Eighth edition. Rewritten and enlarged. Profusely illustrated....$5

STAMP MILLING OF GOLD ORES:
By T. A. Rickard, M. E. An actual record of milling practice in this and other countries. Deals with the erection and management of mills, and contains many helpful suggestions. Well illustrated. Cloth....$2 50

MINERS' POCKETBOOK:
A reference book for miners, mine surveyors, geologists, mineralogists, millmen, assayers and metallurgists. By C. G. W. Lock. 472 pages, illustrated, flexible leather....$5

MANUAL OF MINING:
For the use of Mining Engineers and Technical Schools. Treating of Preparatory and Exploratory Work, Methods of Mining, Hoisting Machinery, Pumping, Ventilation Shafts, Tunnels, Blasting, Timbering, etc., etc. By Prof. Magnus C. Ihlseng, E. M., Ph. D. Third, revised and enlarged, edition. 548 pages, 8vo., cloth....$4

THE METALLURGY OF GOLD:
By M. Eissler. Profusely illustrated....$5

THE EXPLORER'S AND ASSAYER'S COMPANION:
Third edition. By J. S. Phillips. A practical exposition of the various departments of Geology, Exploration, Mining Engineering, Assaying and Metallurgy. An exceeding valuable work....$6

CYANIDE PROCESSES FOR GOLD AND SILVER ORES:
By E. B. Wilson, E. M....$1 50

SKELETON MINING REPORT:
Of great practical value to miners and mine owners in making a comprehensive report on mining properties. Useful and convenient to mining engineers as a field notebook. Price, postpaid....50c

QUARTZ OPERATOR'S HANDBOOK:
By P. M. Randall....$2

ALLOYS:
Thurston, 2nd edition....$2 50

ASSAYING:
Furman, 4th edition....$3

HIGH EXPLOSIVES:
Eissler....$4

GOLD ORES:
Treatment of: O'Driscoll....$2

MINERALOGY:
Brush & Penfield, revised edition, $3 50; Dana, 6th edition, $12 50; Dana, for beginners, $1 50; Dana, Mineralogy and Petrography, 12th edition....$2

MINERALS:
"How to Study Them," Dana, 2nd edition, $2; Dana, American locality of mineral, 6th edition....$1

MINING:
Ihlseng, from lectures in Colorado School of Mines....$4

ORE DEPOSITS:
Phillips, revised edition by Louis....$7

METALLURGY:
Eggleston, Silver, Gold and Mercury, 2 vols.$15

TUNNELING:
Blasting, Timbering, Air Drilling, etc.; 1000 illustrations; Drinker, 3rd edition....$25

CHLORINATION PROCESS:
E. B. Wilson....$1 50

HYDRAULIC AND PLACER MINING:
E. B. Wilson....$2

GEOLOGY:
Emmons, $1 50; Scott, $1 90; Le Conte, revised edition, $4; Dana, 4th edition....$5

IRON AND STEEL:
Thurston, 6th edition....$3 50

LITHOLOGY:
Williams, 2nd edition....$3

LIEBER'S CODE:
Bound in leather....$3

Hydraulic Mining in California.

By rapid stages of progression hydraulic mining California was introduced soon after the discovery gold and was the outgrowth of the natural condi- ons which confronted the pioneers. At first the allow local placers in small gulches were attacked, e pan and rocker being the principal mechanical gents used in getting gold. Later the larger can- ons, in which were living streams, were lined with e camps of thousands of energetic, indefatigable iners, who, finding new obstacles daily, quickly in- nted various methods to overcome them. The ng tom, and, soon after, the sluice box were not ng in following the pan and rocker. Where the by the more ambitious miners of other nations.

Ere long attention was directed to the great banks of gravel found scattered all along the foothills of the middle counties of the Sierra Nevada range. The character of these vast deposits of gravel and sand was not understood, but the fact that they contained gold was quickly demonstrated, though the quantity of gold in these deposits was relatively so small that it was evident a large amount of material must be cheaply handled to make the undertaking profitable. Some of the first efforts in this direction were with the ground sluice, by which method the material was more cheaply handled than by shovelling. As a natural sequence came the introduction of the hydraulic method. It was at first a small, insignificant affair. A canvas hose was the conduit for the water which operated under a low head, but its usefulness was at once recognized and the new method grew rapidly in favor and was applied wherever practicable, the expense of obtaining water, the construction of dams, flumes, ditches and all the paraphernalia being, of coure, considered. In the operation of a gravel mine by the hydraulic method it became evident that there were two important considerations; first, the obtaining of a large quantity of water under high pressure, the expense of which should not be prohibitory; second, a grade below the bank which would afford sufficient fall for the sluices and a dump for the tailings. The various enterprises established from this early time grew in magnitude as the success of smaller ventures became assured, until ditches and flumes were projected and built which cost hundreds of thousands of dollars. Reservoirs constructed for impounding water on the Feather, Yuba, Bear and American rivers had a capacity of 50,000,000,000 gallons. The La Grange ditch and flume was thirty-five miles in length and cost $450,000. The Tuolumne county system was 125 miles long. The Park Canal and Water Co., taking water from the Cosumnes river, comprised 290 miles of ditch, eight miles of flume, and one mile of pipe line. The plant cost $2,000,000. The Mokelumne Hill system cost $500,000, and the California Water Co.'s plant in El Dorado cost $600,000. These are but a few of a score or more of similar undertakings. It is estimated that when hydraulic mining was prohibited that not less than $100,000,000 capital had been invested in these enterprises.

The duty of the miner's inch varies considerably with the character of the gravel and amount of pressure, and also upon the quantity of water used. The accompanying illustration is that of the North Bloomfield mine in Nevada county, Cal., piping with six giants discharging more than 2500 miner's inches of water under a pressure which would instantly kill a man should he be unfortunate enough to be struck by one of these powerful streams. The gravel banks range from a few feet to several hundred feet in height. Many methods are employed to facilitate the disintegration of the gravel where it is firm. Bank blasting is practiced with good results. Excavations are made at the base of the bank and lateral drifts run. Large charges of powder are exploded which shatters the ground and the streams from the giants become much more effective. In some portions of the State, as about Dutch Flat and Gold Run in Placer county, the entire topography of the country has been changed.

THE NORTH BLOOMFIELD HYDRAULIC MINE, NEVADA COUNTY, CAL., PIPING WITH SIX GIANTS.

old was won from bars above the level of the stream ttle difficulty was experienced, as water was con- ucted upon the bars by ditch and flume, and the round sluice was the natural outcome. But it was oon learned that gold existed in large quantity in he channels of the streams, in many of which the mount of water was so great as to make sluicing npossible. The miners overcame this difficulty, in umerous instances wing-damming the streams and n some places turning the stream into a ditch or ume having sufficient capacity to accommodate the ntire amount of water coming down the canyon. his left the river bed below comparatively dry and he gold was recovered rapidly. The first two or hree years made such inroads upon the modern lacers that one locality after another was aban- oned by white miners, who left the Chinese to clean p the tailings and poor spots and many of the lat- er made fortunes from the claims thus abandoned

The Genesis of Petroleum and Asphaltum in California; Telluride Ores, 320. The Alluvial Deposits of Western Australia, 321. Two Recent Stamp Mills; Joint Location of Placer Ground; Exposition Projects; Jeanesville Improved Mine Sinking Pump, 322. Industrial Notes; Personal; Commercial Paragraphs; List of U. S. Patents for Pacific Coast Inventors; Notices of Recent Patents, 326. California Mining Incorporations; Recently Declared Mining Dividends, 338.

If any one industry more than another is entitled to be called a "business," it is mining. "Business" is simply the systematic supplying of wants, and the product of the mine is wanted about as universally as any natural product possibly can be.

It is estimated that the capitalization of trusts formed since Jan. 1st, '99, amounts to $500,000,000, which may be considered a fairly good start for the current year. Several other combinations are now under consideration, which will help to keep up the usual record and hasten the inevitable reaction.

The relation of railways to the mining industry has been clearly demonstrated in Colorado the past winter. Without the roads in operation many of the leading mines were obliged to suspend operations. In some parts of the State the mines could not be operated at any time profitably were it not for the railways.

Huge trusts continue to absorb many industrial organizations, and since the first of the year the movement has developed into a craze similar to that which overspread Great Britain just ten years ago. The aggregate of capitalized stock in the recent combines now runs into the thousands of millions, and, naturally, Eastern bankers and brokers grow apprehensive of so much sail and so little anchor, and are beginning to decline that class of security as collateral. The present activity is a repetition of former history in this regard. Former history shows that that species of speculation ends in a collapse. It is probable that the ultimate result of the present tendency to form trusts in all lines of industrial manufacture or production will result in disastrous reaction.

It is a difficult matter for the owner of a prospect to fix a proper valuation on his prospect, for the reason that if it is a prospect and not a developed mine, his property has a speculative value only. As a matter of course the possible investor is going to use every effort and argument to get the lowest possible price, and often his offer is so far below what the claim owner had set his mind upon that they cannot arrive at a mutually agreeable understanding. The claim owner often loses sight of the risk the investor must take in equipping even a promising prospect, and fixes his price at a sum which he thinks will meet his present requirements and leave a small fortune as well for the future. In the case of mines having considerable development it is somewhat different; the deal resolves itself into a commercial transaction, the element of uncertainty not being so prominent. But when this condition of affairs is reached the prospector usually places his price proportionately high.

Copper Production.

The chief present interest in mining still centers in copper. The magnitude of operations attracts universal attention, and the present profit of production, of course, greatly stimulates the quest for copper properties, a search that in California, Colorado and other states must certainly prove successful. Already Arizona as a copper producer is well in line with Michigan and Montana, and in other sections the stimulus of demand is daily discovering promising copper prospects.

Unlike other trusts and combines, no amount of combination on the part of leading copper producers can prevent others from discovering and supplying copper, or can permanently raise or lower the world's price for a metal that is in such world-wide demand.

The world's output of copper for the past five years has increased from 324,505 tons in '94 to 424,126 tons in '98, as shown by the following figures:

COPPER PRODUCTION—TONS.

	1898.	1897.	1896.	1895.	1894.
Australasia	18,000	17,000	11,000	10,000	9,000
Canada	8,040	5,905	4,000	4,000	5,000
Chili	24,850	21,900	23,500	22,075	21,340
Cape	7,060	7,440	7,450	7,080	6,500
Germany	20,085	20,145	20,065	16,555	17,300
Japan	25,175	23,000	21,000	18,430	20,050
Mexico	10,435	11,370	11,150	11,620	11,770
Spain and Portugal	53,245	54,060	53,325	54,950	54,175
United States	234,271	216,060	203,893	172,300	159,695

The demand has increased in like ratio. With the reopening of properties formerly worked, the discovery and development of new mines, and the increased product of present big producers consequent upon existing high prices, it is within bounds to assume, so far as the United States is concerned, that the 1900 copper product of the country could be made 250,000 tons, did the next eighteen months hold promise of existence of the present high price. At various times have been given herein authentic statements as to the cost of producing copper in various localities. From official reports of several prominent companies, it appears that the recent cost price of pure copper at the Anaconda, Montana, was $113 per ton, or less than 5¾ cents per pound; the cost at the Boston & Montana plant was reported as practically the same; as also the cost at the Calumet & Hecla, Michigan, mine; in each case there being a reduction from the comparatively recent cost of production—$162 per ton, or over 8 cents per pound; this reduction being in each case largely due, not to any increase in the value of the ore, but to improved and more economical methods, and the utilization of "by-products." These prices compare favorably with those furnished by foreign producers. The Newfoundland Copper Company is credited with ability to produce pure copper at $88 per ton, this being probably due to the advantageous shipping facilities of that concern. At Tilt Cove the production price is stated to be $163 per ton, and the old Rio Tinto of Spain reports cost of $124 per ton. In the last-named case the mine is most favorably situated, viewed as a commercial competitor.

The closing down of the 20-stamp mill of a leading Tuolumne Co., Cal., mine, for the alleged reason that ore could not be furnished fast enough for it, is an illustration of the short-sighted policy too often pursued of not keeping the work of exploration in a mine well in advance of stoping. There have been numerous instances of this practice in California. There is nothing which gives mining such a secure footing in the financial world as a long continued, judiciously regulated output. When a mine is so handled as to make a regular monthly output of a stated amount it should be done, and there are few mines that amount to anything where this cannot be accomplished. It is not best to set the mark too high, but at a medium figure which can easily and surely be reached and maintained. Every mine has rich and low-grade stopes, or streaks, in the veins. When the output is found running too high it can be equalized by extracting ore from the low-grade stopes, and if too low it can quickly be brought up to the desired amount. Many well regulated mines pursue this course, and the result is their output is uniform, or nearly so, and there is always more ore in sight in such a mine than in one which each and every month strives to produce a maximum output. When the latter course is pursued there is almost certainly a great difference in the monthly cleanup. It cannot be steadily maintained, and as a natural outcome the mine is gouged and often many ton of low-grade ore, but still ore which will pay, are left behind and eventually lost because of caving of ground or from some other cause, and its recov then becomes expensive. When the policy sugges is pursued the mine so managed comes to be loo upon as a legitimate and secure investment.

Elsewhere herein will be found one of the se of interesting articles on the alluvial deposits Western Australia in which appears the followi "The cement is underlain by a clay which is esse ally a steatite, and is as readily traceable to neighboring diorite as the kaolin at Kintore was ducible from the granite. The green color of cement is imparted by chlorite, derived from decomposition of the epidote in the diorite." Cl chemically considered, results from the decompo tion and disintegration of aluminous silicates, pari ularly feldspar. Clay is also often the mechani result of fine comminution of rocks. Quartz sufficiently fine crushing becomes clay under so conditions. Steatite is a secondary product of m erals containing but little alumina and bears no lation to clay. The component parts of steatite a all secondary; chlorite, talc and calcite are the esse tial constituents. Kaolin may be derived fr granite by alteration of its feldspars, but that ch rite is derived from the epidote in diorite is tremely doubtful. Epidote is not an essential c stituent of diorite, but occurs as an accessory gredient resulting probably from the alteration chlorite, which was derived from the amphibole the diorite. Chlorite is hydrated silicate of ma nesium, iron and aluminum, and epidote a hydro silicate of aluminum, iron and calcium.

The drouth in California is a thing of the pa Since the 15th inst. there has been an almost stea fall of rain in the valleys and foothills and snow the Sierras, and those who have pointed to dry hi and dusty channels as an excuse for inactivity mu conjure up some other reason for individual failur While the dryness of the past eighteen months h been the cause of enforced idleness to many willi workers, yet it has also served as a good excuse f those too lazy to work and who prefer to throw t blame on the weather or any other deterrent caus It is this class who mostly talk of "hard times Times are always hard with men who do not want work, who try to make it appear that somethin else beside themselves is the cause of their failure their poverty, and who, acting as though their nam were forever stricken from the muster rolls of dut seem content to slip down the back entry of Time musty oblivion.

A little mining "boom," with which (with th exception of Colorado) this west half of Ame ica has had but little to do, has revitalized zin Zinc ore has soared in price, and in zinc smelting lively metallurgical contest on economic basis b tween smelters using coal and smelters using gas fuel has resulted in a large transfer of the zin smelting industry to the Kansas natural gas bel From an average of $22.50 per ton in '97, the pric of zinc ore rose last December to $40. As in othe lines it is now proposed in Missouri and Kansas t organize a "zinc miners' association" and regulat supply, grouping the mines, and shutting them dow or resuming production according as surplus o scarcity of ore exists. It is not impossible to formu late such an idea, but the man who will have charg of the details will not have a particularly happy tim of it.

There are a great many books in circulation fo the use of prospectors, all of which contain man good "hints" and much information, but in most o these volumes is found a vast amount of materia calculated to give a "smattering" of scientifi knowledge, which the prospector does not need an which leads him estray when he reads it. It is no necessary for the prospector to be able to distinguis whether a certain rock is basalt or norite, o whether it is diorite or trachite. What he wants t know is how to determine whether a rock has a valu or not. The "genesis of ore deposits" may be in teresting to the scientific student, but it does no matter to the prospector whether the gold in his or came from below, from above or sideways, so long as it is pay rock.

Concentrates.

DESPITE the drouth, the gold yield of California for '98 exceeded that of '97, contrary to general statement, as the forthcoming official figures will shortly show.

REGARDING the absorption of the Salt Lake City, Utah, smelters by the trust, it is understood that the Germania stockholders get $276 per share for their 5000 shares.

THE new county of Ferry, taken from Stevens, is said to have the richest gold and the richest silver mine in the State of Washington—the Republic, in Eureka district, and the Zala M., in Sheridan camp.

ON pages 316, 317 and 318 of this issue appears the full text of the recent decision in the Argonaut-Kennedy case, Amador Co., Cal., accompanied by geological reports from two mining engineers. It will be appealed to the California State Supreme Court.

MINING MEN everywhere are invited to consider this paper as an open forum for discussion of any subject in connection with mining and metallurgy, as interchange of opinion and experience is of general and constant value to the mining industry.

WHILE the law accords the right to a patent to the later applicant who connects by due diligence a prior conception, the reduction to practice must be made by the applicant himself, or by his authorized agent, and not by some other third party.

THE "wonderful" mining discoveries in the far North, duly announced simultaneously with the advent of spring, are to be taken cautiously, and should not unduly influence those to whom transportation companies look to recoup some of last season's losses.

IN dense smoke per ton of coal burned are from ten to twelve pounds of soot, 10 to 15% ash and about 2% moisture. No smoke is produced when fuel is burned in an atmosphere of oxygen. Where no hydrocarbons exist, smoke cannot be produced in any atmosphere by any fuel.

AS IN rivalry to the "embalmed beef," the Klondike, which has just heard of it, sends from Dominion creek a statement that "a prehistoric mammoth, weighing thirty tons, with flesh still sweet enough to eat, was found on Feb. 8th by two miners, while working their claim, 40 feet from the surface."

TO MAKE the extent of fine cracks in tools, etc., visible, it is recommended to moisten the surface of the cracked article with petroleum, to rub off clean and to wipe the surface with chalk. The petroleum which has entered the fine cracks sweats out and the rent is made visible in its whole extent.

FROM Colorado and Utah come reports that not in thirty-five years was there such an unusual snowfall as that of this season. California's snowfall was tardy, but since the 15th inst. more has fallen in the high Sierras than during any season since 1889. This great depth means plenty of water and a busy season for miners.

IN the interests of a prospective copper combine, Montana's Legislature has passed over the Governor's veto a bill empowering the owners of two-thirds of the stock of a corporation to compel the holders of the rest of the stock to sell out at an appraised valuation or to accept stock in another corporation for their holdings.

CONTINUOUS possession of a mining claim, with due compliance of law, for a period equal to the time prescribed by the statute of limitations for mining claims, in the State wherein such claim is situated, entitles the claimant, under the provisions of Sec. 2332, Revised Statutes U. S., to a patent in the absence of any adverse claim.

THERE is some mining activity at Randsburg, Kern Co., Cal., mining there getting down to a substantial business basis, as it usually does in all new camps. Some of the former floating population has scattered out over the desert, seeking new fields, penetrating to Death valley and beyond. Some of these men have already made discoveries.

AS BETWEEN copper and aluminum, it is calculated that two-thirds of a pound of aluminum wire has the conductive capacity of a pound of copper. The former is quoted at 30 cents per pound, the latter, 21. Aluminum is the feed wire for the new Blue Lakes-Stockton line in California, at Snoqualmie Falls, Wash., and for a Chicago elevated railway.

TO DETERMINE the value of a gold specimen in quartz, basing the calculation on the relative densities, one way is to divide the specific gravity of gold by that of quartz, and also by that of the specimen; from the greater quotient subtract the lesser; the remainder is the proportion of gold; from the lesser subtract 1; the remainder is the proportion of quartz.

G. MCDOWELL, at Vancouver, B. C., who represents a Colorado syndicate, says he has come to an agreement with officials of the Canadian Pacific Railroad for a site on which he will build ore sampling works at Nelson. A thirty years' lease will be given for property. The work must commence within three months and be finished in six. McDowell says the works will be completed long before the specified time.

IT is possible, but not probable, that most exact assay might determine an inappreciable percentage of silver in a $20 gold piece, if weighed on scales so delicate as to weigh the unexpressed thoughts of an infant. The "fineness" of gold indicates the number of parts of pure gold in 1000 parts of an alloy—in U. S. gold coins, 900; that is, of 1000 parts of the alloy taken to make those coins, 900 parts are pure gold.

BOILER WATER may be heated almost to the boiling point by utilizing the exhaust steam from the engine A great many devices for accomplishing this are in use. One of the simplest is to pass the exhaust pipe through a cylinder which is filled with water. Only a small percentage of the heat of the steam is utilized by this means, but it will heat the water, which will be found to effect an important saving of fuel in making steam.

"WHEN a locator locates a mining location" crosswise of the vein, his "side lines" become end lines. Then his true side lines must be constructed with reference to the ascertained course of the vein—parallel with and not more than 300 feet on each side of its center. Should the originally marked width prove more than 300 feet, the excess should be discarded, so that the middle of the vein shall be in the center of the location. Such excluded area is subject to appropriation.

WERE the barometric reading on the summit of Mt. Shasta, in California, to be 19.5 in., and at sea level 30 in., the height of the mountain would be determined by the following formula: $\left(\frac{27{,}000 \times 30}{19.5}\right) - 27{,}000 = 14{,}538$ feet. In this, 27,000 feet is figured as the height of the homogeneous atmosphere. (It is believed, however, that more exact data would indicate the height of that peak to be about 100 feet less than the above result.)

CARBONS in diamond drills are usually reset after 40 feet of quartz or 150 feet slate. These and their settings constitute the greatest item of expense. Six 3-carat stones are used to each bit, and they cost about $15 per carat; as it costs $10 to set a bit, this would make each bit cost $280. The cost of wear and tear per foot varies from 30 to 50 cents, according to the hardness of the rock. The entire cost per foot foot of ground drilled would probably average 65 cents. An average drill, including, say, 600-foot rods and two bits, would cost about $2000.

GOLD occurs in calcite in the Alvord mine, twenty-three miles northeast of Daggett, Cal., and in the Carbonate mine at Oro Grande, in San Bernardino Co., Cal.; at Hedges, Cal., in an aggregate of mica scales and in partly altered hornblende; in El Dorado Co., Cal., in feldspar (albite); at Soulsbyville, Cal., in granodiorite; near Big Oak Flat, Tuolumne Co., in a diorite dike; on Castle creek, Arizona, fifty-five miles southeast of Prescott, in an aggregate of scales of specular iron; at Black Hawk mines, San Bernardino Co., Cal., in limestone.

IN the case of Hooper vs. California, 155 U. S., 648-652, the Supreme Court held that "the right of the Legislature to regulate the transaction of business by foreign corporations in this commonwealth, or to forbid it altogether, is beyond question." Still, notwithstanding this, and the enactment of a State law known as the "alien act," bearing directly upon this subject, it is manifest that the whole idea and intent is to hold all this as reserve power and not to actively discourage any alien acquisition of mining property or any other form of real estate.

TWO BILLS passed both houses of the California Legislature last Saturday, one prescribing the manner of locating mining claims upon the public domain of the United States, recording notices of location, amending defective locations, and prescribing the effect to be given to recordation of notices of location, the other repealing the act of March 26, '97, prescribing the manner of locating mining claims, and at latest accounts were in the hands of the Governor, who declined to say whether he had or had not signed them. Without his signature they will not become laws.

THE best procurable data on the question of the treatment of ore at the Bingham, Utah, mine, is as follows: the ore is quartz, iron oxide and lead carbonate; the capacity of the plant is forty tons per day; size of ore leached mesh ¼ inch; the preliminary treatment is sodium dioxide; the strength of the cyanide solution is 0.025 to 0.125; number of hours leached, 120; 1 pound of cyanide is consumed to each ton of ore treated; .30 of 1 pound of zinc is so consumed; the ore assays ¼ ounce per ton gold, and 2 ounces silver; the per cent of gold extraction is 80, at a cost of $1.85 per ton.

FOR a general treatment of ore, smelting, perhaps, is the most universally satisfactory. It is hard to say whether gold ore always does or does not require roasting preparatory to "leaching." The question is one that must necessarily be answered by local conditions—always suiting the process to the ore, not the ore to the process. In the case of tellurides the gold may be extracted by fine grinding and treating with cyanide, though cyanide action on tellurides is slow, and, as a matter of economy, it might be well to give the ore a preliminary roast, care being taken to obviate volatilization.

W. C. RALSTON of San Francisco will this season expend about $300,000 in further development of the property of the Melones M. Co. on Carson Hill, near Robinson Ferry, Calaveras Co., Cal. Among other things he will build a 120-stamp mill, run about 4000 feet of additional tunnel, build a concrete dam and two and one-half miles of ditch. In the issue of Nov. 5th, '98, was published an account (since reproduced all over the world) of fast and economical tunneling work on this property, a 7x8-foot tunnel or drift, 2608 feet in length, being driven through greenstone, slate and quartz stringers at an average of 10¼ feet per day, at a total cost of $11 per running foot.

METAL miners in the region west of the 100th meridian would consider some mining customs further east curious, though, from the working miners' standpoint, not wholly objectionable. According to local statements, the miners in the copper mines of Ontonagon county, Mich., have all along been claiming all the silver they found, as the mining was "for copper only," and, in the case of any silver, the company or mine owner wasn't "in it." This, of course, applied only to "tributers," who usually got 5 cents per pound for the copper they got out. Now, however, companies incorporating have a special clause intended to cover the ownership of any silver incidentally found in the search for copper.

SINCE July 1st, '98, the old construction of the Federal mining law affecting the patenting of mining claims is superseded by paragraph 53 of the new mining regulations, which reads as follows: "The claimant at the time of filing the application for patent, or at any time within the sixty days of publication, is required to file with the register a certificate of the Surveyor General that not less than $500 worth of labor has been expended, or improvements made, by the applicant or his grantors, upon each location embraced in the application, or if the application embraces several locations held in common, that an amount equal to $500 for each location has been expended upon, and for the benefit of the entire group; that the plat filed by the claimant is correct; that the field notes of the survey, as filed, furnish such an accurate description of the claim as will, if incorporated in a patent, serve to fully identify the premises, and that such reference is made therein to natural objects or permanent monuments as will perpetuate and fix the locus thereof; *provided*, that as to all applications for patent made and passed to entry before July 1st, '98, or which are by protests or adverse claims prevented from being passed to entry before that time, where the application embraces several locations held in common, proof of an expenditure of $500 upon the group will be sufficient, and expenditure of that amount need not be shown to have been made upon, or for the benefit of, each location embraced in the application." It will be observed that the $500 need not be expended "on" each claim where the application comprises several locations, but "for" each claim. The aggregate amount in such cases must represent as many times $500 as there are locations, and in such case the entire amount can have been expended on one of the claims provided it can be shown that such amount tended to develop or improve the entire group.

THE following is a simple yet accurate formula for determining the volume of water a given sized pipe with a given fall will furnish, or for calculating the size of pipe required where the maximum quantity of water is known. For velocity in second-feet, for rough pipe, let V = velocity, D = diameter of pipe in feet, and H the fall in feet per 1000 feet. $V = \sqrt{D \times H \times 1.5}$. The quantity delivered by the pipe line can be found by the formula $Q = D^2 \sqrt{D \times H}$, in which Q = quantity in gallons per minute, D = diameter of pipe in inches, and H = fall in feet per 1000 feet. The last formula gives $D^5 = \frac{Q^2}{H}$; that is, knowing the quantity desired in gallons, and the proposed head of pipe line to point of delivery, the diameter in inches of pipe required can be found by dividing the square of the quantity by the fall in feet per 1000 feet, and extracting the fifth root of the quotient.

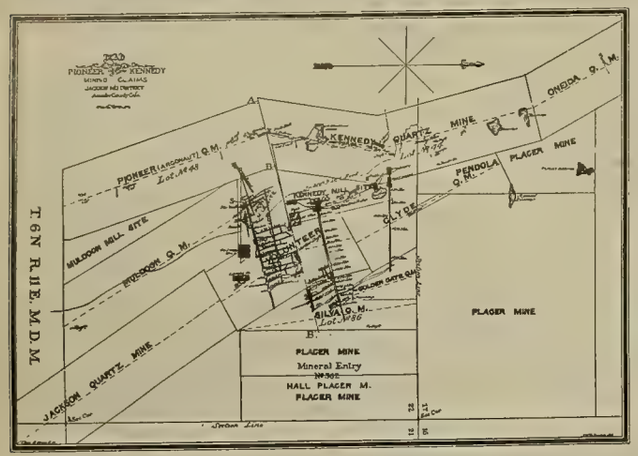
THE first mortar at the Homestake mill, Lead City, South Dakota, weighed 5400 pounds and was 54½ inches high, 54¾ inches long; feed opening, beginning 6½ inches below the top, 24 inches long, 4½ inches wide and 7 inches deep; on entering the mortar it remained 24 inches long and 7 inches deep. At the bottom of the feed, forming the continuation of the incline over which the ore passed into the mortar, was a lip, 4¾ inches wide and 1¼ inches thick, designed to discharge the ore against the upper half of the stamp head; lower edge of lip, 14 inches above the inside bottom of the mortar; 15¼ inches from the bottom was the discharge opening, 48½ inches long and 21¾ inches high, the frame inclined outward about 10° from the vertical; on the short sides of the discharge opening were grooves to receive the chuck block, screen frame and curtain, held in place by keys and sockets; the chuck block fastened at the bottom by two horizontal keys, supported by lugs on the outside lip of the mortar below the discharge. The bottom of the mortar (the mortar bed) was 7¼ inches thick, the sides, at the foot of the dies, 3½ inches; inside dimensions: width at bottom, 10½ inches; length, 50 inches; height to issue of mortar (not of pulp), 8¾ inches; width at that point, 13⅝ inches; at the top of the discharge opening, 20 inches; at the top of mortar, 16 inches; total inside height, 47 inches; casting, ¾ inches thick, from the top down to the feed opening, on three sides, the back being a little thicker.

"WHY do you want to sell your mine or prospect if it is so good a thing as you seem to think? Why don't you keep it if, as you say, the possession of a few thousands would make it so valuable and raise the money?" are questions often asked a mine claim owner. It may, in return, be asked why does any one, anywhere, want to sell anything that he owns. It at once raises the other question, why does any one, anywhere, want to buy anything? Things are mostly bought and sold for convenience and profit. Why does a farmer want to sell his farm; why should any one buy it; why should a city resident want to sell his lot or his house; why does any one want to buy such a piece of property? All these "whys" sound silly—as silly as that oft-asked question of the prospector. As well might the foundryman ask him from whom he buys his pig iron, "Why do you want to sell this raw material? Why don't you yourself make castings of it?" As well might the miner ask the maker of machinery, "Why do you want to sell this concentrator, or hoist, or engine, or pump; why don't you use and operate it yourself?" A prospector or owner of a mine wants to sell from a variety of motives; he may lack (usually does) the money necessary to properly develop the mine (for mines are made), or he may have tired of beans, bacon, black coffee and camp bread, and may want to see and taste other things; or, if he has a good developed property, he may want to sell it for less than it is worth to give himself or his family a desired change. But in any event, it is not in order to ask or quibble as to the motives of any would-be seller of mines any more than of anything else. The business proposition for the buyer is not to ask the vender, "Why do you want to sell?" but to ask himself, "Why do I want to buy?" All this as to the actual mine owner. As to the promoter, the intermediary, the middleman—but that is another story.

GRANITE and syenite look much alike to a casual observer. They cannot be distinguished by the texture. The essential constituents of granite are quartz, orthoclase (potash) feldspar and mica, either black or white. This is simple granite; but in this rock also occurs numerous other minerals, most of which cannot be distinguished without the aid of the microscope. Syenite consists of orthoclase feldspar and hornblende—quartz not an essential constituent, but often occurs. Diorite differs from the above in the character of the feldspar. Its essential constituents are hornblende and plagioclase (soda-lime) feldspar. When quartz occurs it is called quartz-diorite, and when mica is present, as well, it is known as quartz-mica-diorite. Magnetite often occurs so abundantly in the fine-grained varieties as to give the rock a black color. Diorites range in color from light gray to green and black. Typical rocks are rare. They usually graduate from one variety to another, and the name is usually applied in consideration of the most prominent constituents. In California the granite of the Sierra Nevada contains the essential constituents of both typical granite and typical diorite—hence the name grano-diorite. Phonolite is usually rather fine-grained, dark and compact, and when struck gives out a ringing sound. It would be impossible to identify the rock without a great deal of knowledge of the rock-forming minerals. In the Black Hill's phonolite the principal constituents are nepheline, sanidine, ægirine, noselite and sodalite—minerals familiar only to students of petrography. Porphyry is a name employed to designate a rock having distinct crystals occurring in a ground mass of finer grain, as quartz porphyry and granite-porphyry, meaning a granite of even grain, in which occurs large crystals of feldspar. Porphyry does not mean any particular kind of rock, but has reference to the structure only.

Decision in the Argonaut-Kennedy Case, Amador Co., California.

The full text of the decision of Judge G. W. Nicol of the Superior Court of Tuolumne county, Cal., in the case of the Argonaut Mining Co. vs. the Kennedy Mining Co. of Amador Co., Cal., is herewith given in full:



In the Superior Court of the County of Calaveras, State of California.

Argonaut Mining Company (a corporation), plaintiff, vs. Kennedy Mining & Milling Company (a corporation), defendant.

Formerly No. 1408 in the Superior Court of Amador County:

The plaintiff commenced two actions against the defendant in the Superior Court of Amador county, said actions being numbered respectively 1179 and 1408 in the Superior Court of said county Upon the petition of the defendant, the cases were transferred to the Circuit Court of the United States. Motion by plaintiff was subsequently made in the Circuit Court to remand both cases to the Superior Court of Amador county, which motion was granted Argonaut M. Co vs. Kennedy M. & M. Co., 84, Feb 1. Upon the cases being remanded to the State Court, they were removed to the Superior Court of Calaveras county for trial and determination.

The complaint in each action is in the form of an ordinary declaration in trespass, coupled with a prayer for an injunction. The first action was commenced Aug. 11, 1894, to recover $325,000 damages. The second action was commenced Aug. 5, 1897, to recover $125,000 damages for trespasses alleged to have been committed since the commencement of the first action.

The two causes were submitted to the court upon an agreed statement of facts and were both argued together The underlying questions of fact in both cases are identically the same, and the opinion of the court in one will apply with equal force to the other. There is a slight difference as to the defense in the first action from the defense in the second action, but both cases involve a trespass upon the same vein claimed by the plaintiff and differ only as to the locality and the time of the alleged trespasses The arguments of the attorneys were principally directed to the issues involved in the second action, No. 1408, and to those issues the court will direct its opinion.

The facts of the said cause may be epttomized as follows: Plaintiff and defendant are both corporations, organ zed and existing under and by virtue of the laws of the State of California. The plaintiff is the owner of the mining claim designated on Exhibit "A" as the "Pioneer" mine, and the defendant is the owner of the mining claim designated on said exhibit as the "Kennedy" mine; both of said mining claims are patented. The Kennedy M Co. (a corporation), the grantor of the defendant, filed its application for patent for the Kennedy mine on the 13th day of October, 1870; and the Pioneer Gold & Silver M. Co. (a corporation), the immediate predecessor in title of the plaintiff, filed its application for patent for the Pioneer mine on the 13th day of January, 1871.

Thereafter on the 15th day of March, 1871, the Surveyor General of the United States for the State of California issued his instructions to William L. McKin, Deputy Mineral Surveyor, to make survey for patent of said Kennedy mine, and in pursuance of said instructions said McKin, during the months of April and May, 1871, made and completed such survey, and on the 19th day of October, 1871, the said survey was approved by the Surveyor General. On the 11th day of November, 1871, the said Kennedy M. Co entered and paid for said mining claim so surveyed, and on the 29th day of July, 1872, the Government of the United States issued to said Kennedy M. Co. a patent for the said mining claim. On the 28th day of December, 1886, said Kennedy M. Co. conveyed the said mine to the defendant, the Kennedy M. & M. Co.

On the 16th day of June, 1871, the United States Surveyor General, for the State of California, issued his instructions to said William L. McKin to make survey for patent for the Pioneer quartz mine, and on the 1st day of September, 1871, said McKin completed the said survey, and the Surveyor General approved the same on the 21st day of December 1871. On the 23rd day of February 1872, the Pioneer G. & S. M. Co. entered and paid for said mining claim, and the Receiver of the Land Office thereupon issued his duplicate receipt evidencing such entry and payment; and on the 13th day of August, 1872, the Government of the United States issued to the said Pioneer G. & S M Co. a patent for the said Pioneer quartz mine The plaintiff, the Argonaut M Co., became the owner of said mine by deed, executed July 3, 1893, by said Pioneer G & S. M. Co.

The two mining claims are adjoining properties; the line A..B.. marked on the diagram "Exhibit A," is the northern end line of the said Pioneer quartz mine as patented, and to the extent of the length of said line, to-wit: 7 chains and 65 links, is coincident with the southern end line of the Kenuedy mine, and described in the patent of said Kennedy mine. The course of said line A..B.. is north 74 degrees 51 minutes east. The dotted line B....B' is the line A..B.. produced indefinitely in its own direction.

The plaintiff has sunk an incline shaft which has its collar or top in the Pioneer millsite, at a point marked "S" on Exhibit "A," and descends into the earth downward from its collar easterly at an average angle of approximately 62° from the plane of the horizon Traversing said Kenned, and Pioneer mines in a general northerly and southerly direction is a well defined vein, varing in width from 3 inches to 30 feet, said vein dips and descends into the earth easterly at an average angle of approximately 40° from the plane of the horizon until it reaches a point in the Argonaut shaft about 440 feet below the collar th reof, below which point said vein dips and descends into the earth easterly at an average angle of approximately 63° from the plane of the horizon The general direction of the dip of said vein is indicated by the arrows on Exhibit "A." The general course of said vein is S 19 degrees 14 minutes E, or N. 19 degrees 14 minutes W, as is apparent on the surface by the outcrop visible in said Pioneer mine. Said vein in its course southerly passes out of said Kennedy quartz mine, crossing the line A..B.. at a point thereon marked "2" on Exhibit "A," and enters the Pioneer ground; thence pursuing its general southerly course towards the southern end line of the Pioneer quartz mine, which it crosses.

The defendant within the Kennedy millsite at the point marked "X" on Exhibit "A," has sunk a shaft, which is vertical or nearly so to the depth of 305 feet, or thereabouts, at which depth it encounters the vein as it descends from the overlying apex. thence said shaft is an incline following the vein on its dip to the present depth of approximately 1225 feet. From this shaft the defendant has extended levels and drifts southerly on said vein, which are shown in horizontal projections on Exhibit "A," marked 1450, 1550, 1650 and 1750 levels. Some of these levels have been extended on the vein southerly and beyond a vertical plane drawn through the line A..B.. produced in the direction of B.

Between the 8th day of October, 1895, and the 12th day of December, 1895, the defendant extracted and converted to its own use 2604 tons of gold-bearing ore from the said vein southerly and beyond said vertical plane, but within the vertical boundaries of the Silva quartz mine delineated on Exhibit "A."

The gross value of the said ore so extracted and converted by defendant was the sum of $62,218.45. The aggregate cost of mining and milling the said ore was the sum of $6119.40, which amount plaintiff consents may be deducted from the gross value of the ore stated, in the event that the Court should determine that plaintiff is entitled to recover in this action, leaving the sum of $56,099 95 in gold as the net profit realized by defendant from said ore.

The vein exposed in defendant's underground workings south of the vertical plane drawn through the line A..B.. produced in the direction of B is the identical vein which has its top or apex in the Kennedy quartz mine and in the Pioneer quartz mine, and such vein is continuous from the top or apex in both mines downward to the lowest depths, and said vein at all points below the surface continues on its course in a general southerly direction indefinitely towards the south end line of the Pioneer quartz mine, which it crosses, and the said 2604 tons of ore were extracted by defendant from said vein south of the vertical plane drawn through the line A..B..B'. Said vein is the identical vein mentioned in the Kennedy patent as the Kennedy vein or lode and in the Pioneer patent as the Pioneer vein or lode.

The Silva quartz mine, delineated on Exhibit "A" as Lot No. 86, lies to the east of the Pioneer and Kennedy mines. The surface of the said Silva quartz mine overlies so much of the dip of the Kennedy and Pioneer vein as may be found between vertical planes drawn through the boundaries of the said Silva quartz mine. The defendant, the Kennedy M. & M. Co., is the owner of the said Silva quartz mine by virtue of a quartz mining patent issued to it on the 6th day of February, 1893.

No part of the ore bodies in dispute lie between vertical planes drawn downward through the end lines of the Kennedy mine. The defendant, the Kennedy M. & M. Co., makes no claim of right or title to the ores in dispute by reason of its ownership of the Kennedy mine; but it claims title to the ores in dispute by reason of its ownership of the Silva quartz mine. The patent for the Silva mine is in the usual form of patents for quartz mining claims and contains the usual exceptions and reservations. It is presumptively based upon a vein having its apex within the exterior boundaries of the Silva mine. Like all quartz mining patents, it contains the usual reservation that the premises granted, with the exception of the surface, may be entered by the proprietor of any other claim, lode or ledge, the top or apex of which lies outside the boundaries of the granted premises, should the same in its dip be found to penetrate, intersect or extend into said premises, for the purpose of extracting and removing the ore from such other vein, lode or ledge.

The ore bodies in dispute are within the vertical boundaries of the said Silva quartz mine, but are a part of the vein having its top or apex within the Pioneer quartz mine, which vein on its dip to the east extends under the surface of the Silva mine.

At common law a grant of land carries with it all beneath the surface of the earth. In the absence of some one having a better right to the vein which on its dip underlies the surface of the Silva quartz mine, the defendant would own it. The defendant, the Kennedy M. & M. Co., has the right to say, in the language of Judge Hawley, "Hands off of any and everything within my surface lines extending vertically downward, until you prove that you are working upon and following a vein which has its apex within your surface claim, of which you are the owner." (Con. Wyoming M. Co. vs. Champion M. Co., 63 Fed., 540.) For "within the lines of each location the owner shall be regarded as having full right to all that may be found until some one can show a clear title to it as a part of some lode or vein having its top or apex in other territory In other words, we may say that there is a presumption of ownership in every locator as to the territory covered by his location, and within his own lines he shall be regarded as the owner of all valuable deposits until some one shall show by a preponderance of testimony that such deposits belong to another lode having its top or apex elsewhere" (Leadville M. Co. vs. Fitzgerald, 4 Mor. Min. Rep., 380; see, also, King vs. Amy and Silversmith M. Co., 152 U. S., 222; Duggan vs. Davey, 26 N. W. Rep. 887; Doe vs. Waterloo M. Co., 54 Fed., 935; Chessman vs. Shreve, 37 Fed., 36.)

A party claiming the right to follow a vein on its dip under the surface of another person's mining claim is required to show by a preponderance of evidence that he has that right by virtue of his ownership to the vein which has its top or apex within his surface claim and to which is attached under the law an extralateral right.

The end lines of the Pioneer quartz mine, as patented, are not parallel. The northern end line diverges substantially toward the north from a direction parallel to the southern end line; such divergence being to the extent of 14 degrees and 45 minutes northerly from a direction parallel to the southern end line; such divergence between the said end lines is easterly and in the direction of the dip of the Pioneer vein

By reason of such non-parallelism of the end lines of the Pioneer mine, the defendant claims that no extralateral right is attached to the Pioneer, and that the plaintiff has no right to follow the Pioneer vein beyond the vertical boundaries of the Pioneer mine.

The controlling question, then, in this case is: Has the plaintiff the right to follow the Pioneer vein on its dip beyond the vertical plane drawn through the eastern side line of the Pioneer mine? This question is a most important one, and the court has given to it its most careful and earnest consideration.

The patent for the Pioneer quartz mine recites that in pursuance of the Act of Congress approved July 26, 1866, entitled, "An Act granting the right of way to ditch and canal owners over the public lands, and for other purposes," the Act amendatory thereof, approved July 9, 1870, and the Act approved May 10, 1872, entitled, "An Act to promote the development of the mining resources of the United States," there had been deposited in the General Land Office of the United States the plat and field notes of the survey of the Pioneer G. & S. M. Co. upon the Pioneer quartz lode bearing gold, accompanied by the certificates of the Register of the Land Office at Sacramento, in the State of California, whereby it appears that in pursuance of said Act of Congress, the Pioneer G. & S M. Co. did on the 23d day of February, 1873, enter and pay for said mining claim or premises, being mineral entry No. 63 in the series of said office designated by the Surveyor General as Lot No. 48 in the Jackson mining district in Amador county, California, in the district of lands subject to sale at Sacramento, embracing 22.32 acres of land more or less; and which is fully described by metes and bounds.

The following is the granting clause of the patent with the conditions and stipulations annexed: "Now, know you, that the United States of America in consideration of the premises and in conformity with the acts of Congress, have given and granted and by these presents, do give and grant unto the said Pioneer G. & S. M. Co and to their successors and assigns, the said mining premises hereinuefore described as Lot number 48, embracing a portion of the northeast quarter of section 20, in township 6 north of range 11 east, Mt. Diablo meridian, with the exclusive right of possession and enjoyment of all the land included within the exterior lines of said survey, not herein expressly excepted, from these presents, and of 589.94 linear feet of the said Pioneer quartz vein, lode or ledge or deposit as hereinbefore described *throughout its entire depth although it may enter the land adjoining*, and of all the veins, lodes, ledges or deposits throughout their entire depth the tops or apexes of which lie inside the exterior boundary lines of said survey at the surface extended downward vertically although such veins, lodes, ledges or deposits in their downward course may so far depart from a perpendicular as to extend outside the vertical side lines of said survey; provided, that the right of possession hereby granted to such outside parts of said veins, lodes, ledges or deposits shall be confined to such portions thereof as lie between vertical planes drawn downward through the end lines of said survey at the surface so continued in their own direction that such vertical planes will intersect such exterior parts of said veins, lodes, ledges or deposits. And provided further, that nothing in this conveyance shall authorize the grantees herein, their successors or assigns, to enter upon the surface of the mining claim owned or possessed by another. To have and to hold said mining premises, together with all the rights, privileges, immunities and appurtenances of whatsoever nature thereunto belonging, unto the said Pioneer G. & S. M. Co. and their successors and assigns forever, subject, nevertheless, to the following conditions and stipulations:

"First.—That the grant hereby made is restricted to the land hereinbefore described as Lot number 48, with 1589 94 linear feet of the Pioneer quartz vein, lode, ledge or deposit throughout its entire depth as aforesaid, the tops or apexes of which lie inside of the exterior lines of said survey, and to which no valid adverse claim existed on the 10th day of May, 1872.

"Second.—That the premises hereby conveyed, with the exception of the surface, may be entered by the proprietor of any other vein, lode, ledge or deposit, the top or apex of which lies outside of the exterior limits of said survey, should the same in its downward course be found to penetrate, intersect, extend into, or underlie the premises hereby granted, for the purpose of extracting and removing the ore from such other vein, lode, ledge or deposit.

"Third.—That the premises hereby conveyed shall be held subject to any vested and accrued water rights for mining, agricultural, manufacturing or other purposes, and rights to ditches and reservoirs used in connection with such water rights as may be recognized and acknowledged by the local laws, customs and decisions of courts.

"Fourth.—That in the absence of necessary legislation by Congress the Legislature of California may provide rules for working the mining claim or premises hereby granted, involving easements, drainage and other necessary means to its complete development."

It is argued that the said patent for the Pioneer quartz mine in so far as it attempts to grant an extralateral right is absolutely void, as being beyond the jurisdiction of the Land Department of the United States to make such a grant for the reason of the non-parallelism of the end lines of the Pioneer quartz mine.

Numerous authorities are cited to the effect that if the officers of the Land Department acted without authority of law, then their acts are void for want of power to issue the patent. Of the correctness of this proposition there can be no question. The authorities are uniform in holding that a patent issued by the Land Department of the United States to land over which that Department has no power of disposition is absolutely void and conveys no title whatever.

New Dunderberg M. Co. vs. Old, 79 Fed. 598; Rose vs. Richmond M Co., 17 Nev. 25; Reichart vs Felps, 6 Wall. 160; Best vs. Polk, 18 Wall. 112; Sherman vs. Buick, 3 Otto 209; Fanceour vs. Newhouse, 40 Fed 618; Smelting Co. vs Kemp, 104 U. S. 841; Wright vs Roseburg, 121 U. S. 519; Davis' Adm'r vs. Weibold, 139 U. S. 507; Doolan vs. arr, 135 U. S. 624; Deffenback vs. Hawke, 115 U. S. 392; Larkin vs. Dolly, 53 Fed. 333; Larkin vs. Roberts, 54 Fed. 461.

The plaintiff's title to the Pioneer quartz mine was derived under locations made prior to the passage of the Act of May 10, 1872, in other words its right accrued under the Act of Congress of July 26, 1866 This Act was the first general legislation in respect to the disposal of mines. By first section of the said Act it is provided: "That the mineral lands of the public domain, both surveyed and unsurveyed, are hereby declared to be free and open to exploration and occupation by all citizens of the United States, and those who have declared their intention to become citizens, subject to such regulations as may be prescribed by law, and subject also to the local customs and rules of miners, in the several mining districts, so far as the same may not be in conflict with the laws of the United States." The second section gave to the claimant of a vein or lode bearing gold, silver, cinnabar or copper the right to file in the local Land Office a diagram of the same, so extended laterally or otherwise as to conform to the local laws customs and rules of miners, and to enter such tract and receive a patent therefor, granting such mine, together with the right to follow such vein or lode, with its dip, angles and variations, to any depth, although it may enter the land adjoining, which land adjoining shall be sold subject to this condition. Section 3 sets forth the steps necessary to be taken to obtain a patent, and provided that such plat, survey or description shall in no case cover more than one vein or lode, and no patent shall issue for more than one vein or lode, which shall be expressed in the patent issued. Section 4 among other things provided: "That no location hereaf ter made shall exceed 200 feet in length along the vein for each locator, with an additional claim for discovery to each discoverer of the lode, with the right to follow such vein to any depth with all its dips, variations and angles; together with a reasonable quantity of surface for the convenient working of the same, as fixed by local rules; and provided further, that no person may make more than one location on the same lode, and not more than 3000 feet shall be taken in any one claim by any association of persons"

As before stated, the patent for the Pioneer quartz mine was issued on the 12th day of August, 1872. But all the steps necessary to obtain a patent under the Act of 1866 were had and taken by plaintiff's grantor, the Pioneer G. & S. M. Co., prior to the passage of the Act of Congress of May 10, 1872. By sections 2 and 3 of the Act of July 26, 1866, it was provided that a claimant of a lode or vein could file a diagram of the same so extended laterally or otherwise as to conform to the local laws, customs and rules of miners, and enter such tract and receive a patent therefor, granting such mine together with the right to follow such vein or lode with its dips, angles and variations to any depth although it may enter the land adjoining, which land adjoining shall be sold subject to this condition: that upon the filing of this diagram and the posting of the same together with a notice of intention to apply for a patent, the Register of the Land office should publish and post the notice for the period of ninety days, and after the expiration of said period, if no adverse claim has been filed, the Surveyor General should on application of the party survey the premises, make a plat thereof endorsed with his approval, designate the number and description of the location, the value of the labor and improvements, and the character of the vein exposed; and upon the payment of $5 per acre, together with the costs of survey, plat and notice, and giving satisfactory evidence that the diagram and notice had been posted for the period of ninety days, the Register should transmit to the General Land Office the plat, survey and description and a patent should issue for the same thereupon

All of this had been done by the Pioneer G. & S. M. Co. long before the Act of May 10th, 1872, was passed. On the 23d of February, 1872, the claimant of the Pioneer mine entered and paid for the said mining claim and the Receiver of the Land Office on said day issued his duplicate receipt, evidencing such entry and payment. As soon as this payment was made the Pioneer G. & S. M. Co was entitled to a patent. When the Act of May 10, 1872, was passed plaintiff's grantor held the obligation of the Government to issue to it a patent for the Pioneer mine under the Act of July 26, 1866.

"By the mining laws of the United States three distinct classes of title is created, viz.: 1. Title in fee simple. 2. Title by possession. 3. The complete equitable title. The first vests in the grantee of the Government an indefeasible title, while the second vests a title in the nature of an easement only. The first, being an absolute grant by purchase and patent without condition, is not defeasible, while the second, being a mere right of possession and enjoyment of profits without purchase and upon condition, viz., to perform the labor or make the annual improvements required by the State. The equitable title accrues immediately upon purchase, for the entry entitles the purchaser to a patent, and the right to a patent once vested is equivalent to a patent issued." (Benson M. Co. vs Alta M. Co., 145 U. S., 428.)

"When the price is paid the right to a patent immediately arises. If not issued at once it is because the magnitude of the business in the Land Department causes delay. But such delay in the mere administration of affairs does not abolish the rights following from the purchase or cast any additional burdens on the purchaser or expose him to the assault of third persons." (Benson M. Co. vs. Alta M. Co., 145 U. S., 431-432.)

In the case of Stark vs. Starrs, 6 Wall, 402, the United States Supreme Court held that: "The right to a patent once vested is treated by the Government when dealing with the public lands as equivalent to a patent issued. When, in fact, the patent does issue it relates back to the inception of the rights of the patentee, so far as it may be necessary to cut off intervening claimants." In Carroll vs. Safford, 3 How., 441, it is said that "lands which have been sold by the United States can in no sense be called the property of the United States than lands patented, for, as the rights of the purchaser are concerned, they are protected under the patent certificate as fully as under the patent when sold. The Government, until the patent issues, holds the mere legal title for the land in trust for the purchaser." In Cons. Wyoming G. M. Co. vs. Champion M. Co., 63 Fed., 540, and in Walrath vs Champion Co., 63 Id., 552, it is held by Judge Hawley that "a receipt and certificate of purchase from the United States Land Office is the equivalent of a patent," and to the same effect is the decision of the United States Supreme Court in Defferback vs. Hawk, 115 U. S., 392. In People vs. Shearer, 30 Cal., 645-648, the Court, speaking through Mr. Justice Sawyer, said: "By the payment and acceptance of the purchase money the claimant has performed everything to be done by him, and the purchase has been complete ed. The payment, receipt and certificate of entry therefor constitute an entry of the land. The contract of purchase is executed and the land is his, and no longer belongs to the Government. The conveyance has not been made, but the Government of the United States only holds the legal title in trust for the purchaser. The land no longer constitutes a part of the public domain. The United States has ceased to have any proprietary interest in it. It is henceforth private property." * * * When a party pays the purchase money and receives the certificate of sale he is the owner of the land. "The United States has ceased to have any pecuniary interest in it. They hold the naked, dry, legal title for the holder of the certificate." Hamilton vs. Southern Nevada M. Co, 13 Sawy., 113, 33 Fed., 562; Union M. Co. vs. Danberg, 2 Sawy., 455; Amador Medean G. M Co. vs. outh Spring G. M. Co., 13 Sawy., 113, 36 Fed., 668-670; Aurora Hill Cons. M. Co. vs. 85 M. Co., 12 Sawy., 355, 34 Fed., 515.

In Wirth vs. Branson, 98 U. S., 118, Justice Bradley, who delivered the opinion of the Court, speaking of the value, force and effect of proceedings anterior to the issuance of a patent, says: "The rule is well settled, by a long course of decisions, that when public lands have been surveyed and placed in the market a person who

complies with all the requisites necessary to entitle him to a patent in a particular lot or tract is to be regarded as the equitable owner thereof * * *. The public faith has been pledged to him * * *." The authorities are uniform in holding that when a person pays the Government the purchase price of the land and received the certificate of purchase he is then vested with the complete equitable title, and the mere dry, naked, legal title remains in the Government in trust for the holder of the equitable title, in whom is vested all the rights and obligations of ownership. In Benson M. Co. vs. Alta M. Co., 145 U. S., 428. Mr. Justice Brewer, speaking for the United States Supreme Court, uses the following language at page 434: "There is no conflict in the rulings of this Court upon the question. With one voice they affirm that when the right to a patent exists the full equitable title has passed to the purchaser, with all the benefits, immunities and burdens of ownership, and no third party can acquire from the Government interest as against him."

By the foregoing authorities it is established that when on the 23rd day of February, 1872, the purchase price was paid and the certificate of purchase issued the Pioneer G. & S. M. Co. was invested with the complete equitable title, and held the obligation of the Government to issue to it a patent for the Pioneer mine. A patent when granted relates back to the first initial valid step, which is the foundation of the right and in pursuance of which the patent is issued. Kahn vs. The Old Telegraph M Co., 2 Utah, 174, 11 Mor. Min. Rep., 645; Benson M. Co., vs. Alta M. Co., 145 U. S., 428-434; Stark vs. Starrs, 6 Wall, 402; Sly vs. Frisbee, 17 Cal., 350; Yount vs. Howell, 14 Cal., 465; Touchard vs. Crow, 20 Cal., 150; Aurora Hill Co. vs. S. M. Co., 12 Sawy., 355-34 Fed., 515; Eureka M. Co. vs. Richmond M. Co., 4 Sawy., 302.

As the plaintiff's grantor received its certificate of purchase prior to the passage of the Act of May 10th, 1892, and the patent which was subsequently issued related back to the inception of the rights of the patentee, it is clear to my mind that the extralateral rights of the plaintiff may be determined under the Act of July 26th, 1866. When the Act of July 10th, 1872, was passed the plaintiff's grantor was already the owner of the absolute equitable title to the Pioneer quartz mine, and had been such owner ever since the 23rd day of February, 1872, the day on which it paid the Government of the United States the purchase price of the land. The fact that the patent was not issued until the 12th day of August, 1872, is, in my judgment, wholly immaterial. If on account of the magnitude of the business in the Land Department the patent was not issued immediately after the payment, such delay will not cast additional burdens upon the purchaser, nor deprive him of any right which he otherwise would have had. If by the Act of July 26th, 1866, parallelism of end lines was not required, then my opinion is that the plaintiff is entitled to extralateral rights irrespective of the provisions of the Act of May 10, 1872, which makes parallelism in end lines an essential requisite to the existence of any right the locator or patentee to follow his vein on its dip outside of the vertical planes drawn through the side lines.

As before stated, the Act of July 26, 1866, was the first general legislation looking to the disposal of mines. Before its passage the rights of miners upon the public domain of the United States were governed by the local rules and customs of miners. The Act did not interfere with those rights, but was confirmatory thereof. (Walrath vs. Champion M. Co., 63 Fed., 540; Carson City G. & S. M. Co. vs North Star M. Co., 33 Fed., 658; Eureka Cons. M. Co. vs Richmond M. Co., 4 Sawy., 302.) In no provision of the said Act is there any intention manifested to interfere with the possessory rights previously acquired, or which might thereafter be acquired. The intention expressed was to secure them by a patent, and the general purpose of the Act was to give the sanction of the Government to those possessory rights, acquired under the local customs, laws and decisions of the courts. (Jennison vs. Kirk, 98 U. S., 453.) Under these rules the lode was the principal thing, and the surface ground was a mere incident to the same for the convenient working thereof. (Walrath vs. Champion M. Co., 63 Fed., 540; Golden Fleece G. & S. M. Co. vs. Gable G. & S. M. Co., 12 Nev., 312, 1 Mor. Min. Rep., 120.) The location was made for a certain number of feet of the lode and the locator was entitled to the number of feet claimed in whatever direction the lode was found, with its dips, spurs and angles. (Carson City G. & S. M. Co. vs. North Star M. Co., 83 Fed., 658.) By the Act of 1866 the claimant of a lode who had occupied and improved the same according to these local rules and customs of miners, and having expended in actual labor and improvement thereon an amount of not less than $1000, and in regard to whose possession there was no controversy or opposing claim, could receive a patent for the same from the Government of the United States. A party applying for a patent under said Act was required to file in the local land office a diagram of the same, so extended laterally or otherwise as to conform to the local laws, customs and rules of miners, and to enter such tract and receive a patent therefor, granting such mine, together with the right to follow such vein or lode, with its dips, angles and variations, to any depth, etc. Under the terms of the Act of July 26, 1866, "However tortuous might be the course of the lode, the claimant had a perfect right to follow it up and prepare his diagram so as to include it, together with the surface ground on each side thereof allowed by the local laws. There is no language in the Act that requires the diagram to be in the form of a parallelogram or in any other particular form." Wolfey et al. vs. Lebanon M. Co., 4 Colo., 112, 13 Mor. Min. Rep., 235; Carson City G. & S. M. Co. vs. North Star M. Co., 83 Fed., 658-669. "As might be expected, the patents issued under this statute describe surface areas of different and sometimes irregular form. Often they were like a broom, there being around the discovery shaft an amount of ground deemed large enough for the convenient working of the mine, and a narrow strip extended therefrom as the handle of the broom. This strip might be straight or in a curved or irregular line, following, as was supposed, the course of the vein. Sometimes the surface claimed and patented was a tract of considerable size, so claimed with the view of including the apex of the vein in whatever direction subsequent exploration might show it to run. And, again, when there were local rules giving to the discoverer of the mine possessory rights in a certain area of surface, the patent followed those rules and conveyed a similar area." Del Monte M. Co. vs. Last Chance M. Co., 171 U. S., 55-84.

There is no provision of said act that requires the end lines of a mining claim to be parallel, nor is there any intention manifested to make parallelism essential. Up to the passage of Act of May 10, 1872, there was nothing whatever in the Statute which called upon the locator to make his end lines parallel, and it is only by virtue of the Act of May 10, 1872, that parallelism was made essential. The local rules and customs of the miners before the passage of that Act did not require it, nor did the Act of Congress of July 26, 1866. It is said by Mr. Justice Brewer in Del Monte M. Co. vs. Last Chance M. Co. (171 U. S. 87) that, "there is no inherent necessity that the end lines of a mining claim should be parallel." They must be parallel because the statute so specifically provides. (Section 2320 Revised Statutes.) Parallelism of end lines is purely a requirement of the Act of 1872. The object of the statute in this respect was no doubt to prevent a party from claiming more outside his lines than within them. Doe vs. Sanger, 83 Cal., 203. This was one of the evils the Act of 1872 provided against; but a right previously acquired not not interfered with by the Act of May 10, 1872. Section 9 of said Act is as follows: "That Sections 1, 2, 3, 4 and 6 of an Act granting the right of way to ditch and canal owners over the public lands and for other purposes, approved July 26th, 1866, are hereby repealed, but *such repeal shall not affect existing rights.* Applications for patents now pending may be prosecuted to a final decision in the General Land Office; but in such cases, where adverse rights are not affected thereby, patents may issue in pursuance of the provisions of this Act, and all patents for mining claims heretofore issued under the Act of July 26, 1866, shall convey all the rights and privileges conferred by this Act, where no adverse rights exist at the time of the passage of this Act." (Section 2328 Revised Statutes.) The intent of Congress is expressly declared by said section to prepare unaffected all existing rights acquired under the Act of 1866. Congress, instead of designing to interfere with the previously acquired rights, expressly enlarges them, as are the rights of all patentees under the Act of 1866, by granting all veins, lodes and ledges having their tops or apexes within the exterior boundaries of their surface claims. Thus a patent under the Act of 1866 conveyed only the one vein or lode applied for; all other veins were expressly reserved. The said Act provides that the "plat, survey or description shall in no case cover more than one vein or lode, and no patent shall issue for more than one vein or lode, which shall be expressed in the patent issued." (Section 3, Act of 1866.) The effect of the Act of 1872 (where no adverse rights existed) was to grant to such prior patentees all other veins, lodes and ledges throughout their entire depth, the top or apex of which lies inside of such surface lines extended downward vertically in whatever course or direction they might run. (Walrath vs. Champion M. Co., 63 Fed. 552-557.)

That the intent of Congress was not to abridge any of the rights of the miners acquired under the Act of 1866 is further manifested by Section 12 of the Act of 1872 wherein the following language is used: "Nothing in this Act shall be construed to enlarge or affect the rights of either party in regard to any property in controversy at the time of the passage of this Act, or of the Act entitled 'An Act granting the right of way to ditch and canal owners over the public lands and for other purposes, approved July 26, 1866, *nor shall this Act affect any right acquired under said Act;*" and Section 16 provides, "That all Acts and parts of Acts inconsistent herewith are hereby repealed: *provided that nothing contained in this Act shall be construed to impair in any way rights acquired under existing laws.*" The proviso contained in said Section 16 is embodied in the same terms in Section 2344 of the Revised Statutes of the United States.

That the policy of Congress was to preserve previously acquired rights and not to impair them, sufficiently appears by Section 5597 of the Revised Statutes, which section reads as follows: "The repeal of the several Acts embraced in said revision *shall not affect any act or any right accruing or accrued* or any suit or proceeding had or commenced in any civil cause before the said repeal, *but all rights* and liabilities under said Acts *shall continue and may be enforced in the same manner as if said repeal had not been made* * * * *."

It is apparent to my mind from the foregoing provisions of the statute that the intention of Congress was not to abridge but to preserve and continue the rights of the miners acquired under the provisions of the Act of July 26, 1866.

The Act of May 10, 1872, did not curtail and was not intended to curtail or modify any rights acquired under the Act of 1866. None of its provisions are capable of that construction, nor could the Court so construe the Act as to give it a retrospective effect and thereby impair vested rights. Of course, such being the case the extralateral rights of the plaintiff must be determined under the provisions of the Act of 1866.

As before stated there is no provision of the Act of 1866 that requires the end lines of a mining claim to be parallel, nor is there any intention manifested by said Act to make parallelism essential. That the Act of 1866 (under the provisions of which plaintiff's rights accrued) did not require parallelism of end lines has been adjudged in the following cases: Eureka Cons. M. Co. vs. Richmond M. Co., 4 Sawy. 302; Carson City G. & S. Co. vs. North Star M. Co., 83 Fed. 659-669; Walrath vs. Champion M. Co., 63 Fed. 552; Cons. Wyoming G. M. Co., 118 U. S. 196; Carson City G. & S. M. Co. vs. North Star M. Co., 73 Fed. 597.

Upon the question of parallelism of end lines under the Act of 1866 the case of Eureka Cons. M. Co. vs. Richmond M. Co. (4 Sawy 302) is important. The plaintiff, the Eureka M. Co. was the owner of several locations, among which were the Champion, At Last, and the Lupita or Margaret mining claims. The Champion was patented with parallel end lines. But the end lines of the At Last and the Lupita or Margaret as patented were not parallel, *but diverged in the direction of the dip of the vein.* The Champion was located in May, 1870, and was patented in 1872. It did not appear in the record when the At Last and the Lupita or Margaret claims were located. The patent shows that Lupita was entered and paid for on the 14th of February, 1877, and the patent issued on the 30th day of March, 1877. The At Last, as appears by the patent, was entered and paid for on the 29th day of March 1873, and the patent issued on the 12th day of December, 1876. The defendant, the Richmond M. Co., made objection to the validity of the patents to the At Last and the Lupita or Margaret, because the end lines were not parallel, as required by the provisions of the Act of 1872. To this contention of the Richmond Co. Justice Field said: "But to this objection there are several obvious answers. In the first place, it does not appear upon what locations the patents were issued. They may have been, and probably were, issued upon locations made under the Act of 1866, where such parallelism in the end lines of the surface locations was no required. The presumption of law is that the officers of the executive department specially charged with the supervision of applications for mining patents and the issue of such patents did their duty; and the assertion of a contrary mere surmise to the contrary will not be listened to. If, under any possible circumstances, a patent for a location without such parallelism may be valid, the law will presume that such circumstances existed. A patent of the United States for land, whether agricultural or mineral, is something upon which its holder can rely for peace in security in his possession. In its potency it is ironclad against all mere speculative inferences. In the second place the provisions of the Statute of 1872, requiring the lines of each mining claim to be parallel to each other, is merely directory, and no consequence is attached to a deviation from its direction. Its object is to secure parallel end lines drawn vertically down, and that was effected in these cases by taking the extreme points of the respective locations on the length of the lode. In the third place, the defect alleged does not concern the defendant, and no one but the Government has the right to complain."

Unquestionably the above doctrine of the Eureka case in so far as it holds that the provisions of the Statute of 1872, requiring the end lines of mining claims to be parallel, is merely directory and that no consequence is attached to a deviation from its direction has been modified by the United States Supreme Court. Iron Silver M. Co. vs. Elgin M. Co., 118 U. S. 196; Del Monte M. Co. vs. Last Chance M. Co., 171 U. S. 55.

The defendant, the Richmond M. Co., also held several patents issued to it upon different locations, but it specially relied upon the patents to the Richmond and the Tip Top claims. It alleged that these patents were issued upon locations made prior to any upon which the patents to the Eureka Co. were issued; and its contention was that inasmuch as the croppings of the vein were within the surface of the patented locations it had the right to follow the vein wherever it went, although it be outside of the end line planes. Its position was that "whenever under the law of 1866 a location was made on a ledge or vein, a right was acquired to follow the vein wherever it might lead, without regard to the end lines of the location." In the discussion of this contention of the Richmond Co. Mr. Justice Field among other things said: "Now, as neither the rules of miners in Eureka mining district nor the Act of 1866 in terms, speak of end lines to locations made on ledges nor in terms impose any limitation upon miners following these veins wherever they may lead, it is contended that no such limitation can be considered as having existed and be enforced against the defendant. The Act of 1866, it is said, recognizes the right of the locator to follow his vein outside of end lines drawn vertically down when it permits him to obtain a patent granting his mine, together with the right to follow such vein or lode with its dips, angles and variations to any depth, although it may enter the land adjoining, which land adjoining shall be sold subject to this condition.

"It is true that end lines are not in terms named in the rules of the miners, but they are necessarily implied and no reasonable construction can be given to them without such implications. What the miners meant by allowing a certain number of feet on a ledge was that each locator might follow his vein for that distance on the course of the ledge and to any depth within that distance. So much of the ledge he was permitted to hold as lay within vertical planes drawn down through the end lines of his location, and could be measured anywhere by the feet on the surface. If this were not so, he might by the bend of his vein hold under the surface along the course of the ledge double and treble the amount he would take on the surface. Indeed, instead of being limited by the number of feet prescribed by the rules, he might in some cases oust all of his neighbors and take the whole ledge. No construction is permissable which would substantially defeat the limitation of quantity on a ledge, which was the most important provision in the whole system of mining."

The Court is here speaking of the claim of the Richmond Co. under the Act of 1866 to follow its vein wherever it might lead, without regard to the end lines of the location. In the consideration of the Eureka case the fact must not be lost sight of that the Court is here dealing with patented locations. Whatever may have been the rights of a locator under the Act of 1866, to follow his vein or lode wherever it might lead, still when he received a patent, those rights were controlled by the patented lines, and he could not follow the vein on its course beyond those lines. The contention of the Richmond Co. was that it had the right to follow the vein on its strike beyond the end lines and this Mr. Justice Field held should not be done, because if this were so a party "might by *the bend of his vein* hold under the surface along the course of the ledge double and treble the amount he could take on the surface." This does not mean the dip of the vein, but it means a bend on its strike, a change in its course, where it may pass out of and beyond the surface location. The decision in the Eureka case gives to the plaintiff all the ground in dispute lying within planes drawn vertically downward through the end lines of the plaintiff's patented locations. The end lines of the At Last and Lupita or Margaret claims as before stated were not parallel, *but diverged in the direction of the dip of the vein*; and to hold that the language above quoted from the Eureka case requires parallelism of end lines under the Act of 1866, to support the extralateral right would be to ignore the ultimate conclusion reached by the Court. Therefore this language of Justice Field must be applied exclusively to the contention of the Richmond Co. to follow the vein on its strike beyond the end line planes. This doctrine of the Eureka case against the right claimed by the Richmond Co. to follow the vein beyond the end line planes is but the forerunner of the following decisions that subsequently defined the rule that you could not follow the vein on its strike beyond your surface boundaries: Mining Co. vs. Tarbet, 98 U. S. 463; Argentine M. Co. vs. Terrible M. Co., 122 U. S. 478; King vs. Amy and Silversmith M. Co., 152 U. S. 222; Iron Silver M. Co. vs Elgin M. Co., 118 U. S. 196. See also Wolfey vs. Lebanon M. Co., 4 Colo. 112; 13 Mor. Min. Rep. 232. New Dunderberg M. Co. vs Old, 79 Fed. 598.

It is contended by the defendant in the case at bar that the Eureka case was substantially decided upon the ownership by the Eureka Co. of the Champion claim alone; a mining claim which had parallel end lines. With this contention of the defendant I am unable to agree. It is true that the Champion had parallel end lines. But the decision of the Court was not based on the ground of the ownership by the Eureka Co. of the Champion alone, but was based on the ground of its ownership of the Champion, the At Last and the Lupita or Margaret claims.

The Eureka Co. was the patentee of several locations, but for the purposes of the action Justice Field said it was only necessary to refer to three of them: the Champion, the At Last and the Lupita or Margaret claims. The diagram accompanying the opinion (4 Sawy. 304) shows the relative positions of these three mining properties. The Court found that the *top or apex of the lode was within the surface lines of these three mining claims.*" (Finding of fact No. 17.) And as the ground in dispute was within planes drawn vertically downward through the end lines of these patented locations, Justice Field held that the ground was the property of the Eureka Co., and that it was entitled to judgment for its possession.

The Eureka case went to the Supreme Court of the United States, and the judgment in favor of the Eureka M. Co. was affirmed. The Supreme Court after passing upon the comprimise agreement said the Richmond Co. is in no condition to dispute the validity of the Eureka's patents for the At Last and the Margaret because the end lines of the surveys are not parallel as it has agreed with the Eureka, for a consideration not to work in the limestone to the south and east of the compromise line. Upon the face of the patents the United States has granted to the Eureka the right to small veins, lodes and deposits, the tops or apexes of which lie on the inside of its surveys as patented, throughout their entire depth, and wherever they may go provided it keeps itself within the end lines the surveys. The finding that the ground in dispute is within the end lines and that the apex is within the surface lines settles the rights of the parties between themselves as well under their patents as under their compromise agreement." (Richmond M. Co. vs. Eureka M. Co. 103 U. S. 839-847).

There is nothing in Mining Company vs. Tarbet 98 U. S. 463, as I read the decision, that requires parallelism of end lines under the Act of 1866 nor does the decision, as I understand it, qualify the doctrine of the Eureka case (4 Sawy. 302). In Mining Company vs. Tarbet commonly called the "Flagstaff case" a surface location was made which was 100 feet wide by 26 feet long. This location was known as the Flagstaff mine and for which the plaintiff in error held a patent issued under the Act of 1866. It lay across the lode, not along it. The location was made on the supposition that it followed the course of the ledge, but subsequent developments show that it crossed the vein at right angles, so that there was but 100 feet of the vein within the surface boundaries.

The claim of the plaintiff in error was of the ownership of 2600 feet in length of such vein. In other words the contention was that it was the lode which was granted, and that the surface ground was a mere incident for the convenient working of the lode. This contention of the owner of the Flagstaff was presented in the following instruction propounded by the plaintiff in error in the trial court, which instruction the Court refused:

"By the Act of Congress of July 26th, 1866, under which all these locations are claimed to have been made it was the vein or lode or mineral that was located and claimed; the lode was the principal thing and the surface area was a mere incident for the convenient working of the lode; the patent granted the lode as such irrespective of the surface area which an applicant was not bound to claim; it was his convenience for working the lode that controlled his location of his surface area; and the patentee under that Act takes a fee simple title to the lode, to the full extent located and claimed under said Act."

The Supreme Court of the United States in affirming the judgment of the lower court held, that in such case the so-called side lines were in fact end lines and that the locator was restricted to so much of the lode as his claim covers. That the right to follow the dip outside of the side lines was based on the hypothesis that the direction of these lines corresponded substantially with the course of the lode or vein at its apex or near the surface. "It was not the intent of the law to allow a person to make his location crosswise of a vein so that the side lines shall cross it, and thereby give him the right to follow the strike of the vein outside of his side lines. That would subvert the whole system sought to be established by the law." If he locates crosswise of the lode and his claim is only 100 feet wide that 100 feet is all he has a right to. The end lines of a location are those which are laid crosswise of the general course of the vein on the surface, and by those lines the locator's rights must be measured, no matter how he may have located his claim.

The question of parallelism of end lines under the Act of 1866 was not a question before the court in the Flagstaff case; nor does the court in any manner pass upon it.

The case of New Dunderberg M. Co. vs. Old 79 Fed., 598, affirms the rule laid down in the Flagstaff case to the effect that when the side lines of a location cross the course or strike of the veins they constitute end lines and the owner of the claim cannot follow the vein outside of those lines. Other questions were also raised and decided but none of them have any bearing on the question of parallelism of end lines under the Act of 1866.

The case of Carson City G. & S. M. Co. vs. North Star M. Co. 83 Fed., 658, in many of its features resembles the case at bar; except that the end lines of the North Star mine converge, whereas the end lines of the Pioneer mine diverge in the direction of the dip of the vein. But the principal in both cases in my judgment is the same. The application to enter and receive a patent for the North Star mine was made on the 15th day of September, 1899, and the patent was issued on the 11th day of August, 1875. In the North Star case it was contended for the plaintiff in error that because the patented claim of defendant was composed of a number of locations, no extralateral rights were secured to it unless it showed the lines of each separate location. That Section 2322 Rev. St. U. S. refers exclusively to a single location. That if the boundaries comprising the aggregate amount applied for and patented do not appear in the patent, but only the exterior boundaries of the entire aggregated tract then the patentee, if he claims the extralateral right as to any vein, the apex of which is found within the surface of his aggregate tract, should be held to establish by proof where some location was, and how it was laid upon the ground, or be denied the extralateral right.

The court held that this contention could not be sustained. "That the defendant was not required to show the separate lines of any of the original locations embraced within the surface boundaries of the patented claim." It was enough for it to show that a lode running in an easterly and westerly direction (lengthwise with the claim) and having its apex within the surface boundaries of the defendant's patented ground, extended, in its dip downward into plaintiff's ground.

The Court then discusses the rights conveyed by a patent and the presumptions in favor of patents regularly issued; citing authorities to the effect that the issuance of the patent is conclusive as to all precedent acts and facts which the land department must find to exist before the patent can rightfully issue.

As to the end lines of the North Star claim not being parallel, the court speaking through Judge Hawley said:

"The plaintiff in error contends that if the patented area of the North Star is to be considered as a location its end lines are not parallel, as found by the court, and that under Section 2320 Rev. St., the defendant possesses no extralateral rights under it. The Act of 1866, under the provisions of which the patent in this case was applied for, and under which the rights of defendant in error accrued, did not require parallelism of end lines."

From the foregoing it follows, that the plaintiff possesses extralateral rights, and is entitled under its patent to follow the Pioneer on its dip beyond the vertical plane drawn through the eastern side line of the Pioneer mine.

As to the question of interest, my opinion is that under Section 3287 of the Civil Code the plaintiff is only entitled to recover interest from the date of the stipulation.

I have examined the numerous cases cited with care and after a most careful consideration of this case my conclusion is that plaintiff, the Argonaut M. Co. is the owner of the ore bodies in dispute and that it is entitled to judgment. And it will be so ordered.

Dated March 13th, 1899.

G. W. NICOL, Judge Presiding.

(Endorsed)

Filed March 15, 1899, by J. S. JACK, Clerk.

The following is from two reports made in September, '98:

Geology of the Argonaut Vein.

In the Argonaut and Kennedy mines is found a perfect example of that class of mineral deposit known as and called a "true fissure" vein. By the term "true fissure" is meant a vein or fissure which cuts through rock formations of either similar or unlike character, wholly independent of either the dip or strike of the rocks which form the walls of the vein.

Veins of undoubted fissure type do occur, however, which conform with strike or dip of the wall rocks, and in some instances with both.

That the Argonaut vein is persistent for thousands of feet

in both strike and dip is abundantly proven in the extensive workings of the Argonaut and Kennedy mines, connection of their levels at numerous points showing clearly the identity and continuity of the vein in these mines.

The geology of the vein is very simple and may be briefly stated. That geological horizon known as the "Mariposa Beds" (U. S. Geological Survey), which here, as elsewhere in California, consists of finely laminated black clay slates, is found intruded by dyke-like masses of diabase.

These are of varying width and appear to have been thrust in from the northward, where, at a distance of 1000 feet or thereabouts, to the northward of the Argonaut shaft along the base of the Reservoir hill, the diabase seems to have almost wholly displaced the clay slates. To the westward of the most westerly of these slate strips is found a broad area of diabase mostly massive and granular, extending many thousands of feet to the northward and southward.

When in their normal position and condition we find the slates of the "Mariposa beds" along the "gold belt" almost universally dipping to the eastward and striking a few degrees west of north. In the Argonaut mine local disturbances have resulted in folding, faulting and crushing these slates, the degree of foliation and alteration appearing in proportion to the amount of crushing and shearing to which the rock has been subjected. Whether or not the cleavage planes of the slates are coincident with the planes of sedimentation cannot be determined, nor is it important.

The diabase has also shared in this alteration from the same causes, namely, movement and fracture of the rock masses due to tremendous compressive stress resulting in a process of crushing and shearing of this hard, tough, granular rock and its consequent alteration to splintery, schistose and slaty rocks with every phase of transition from granular normal diabase to chloritic slate and schist. (Amphibolite schist U. S. G. S.) Diabase when so altered to a slaty condition forms the "gray slate" of the miners.

The slaty structure in these rocks is often so perfect that is some instances, particularly when found in the vicinity of the black clay slates, where the chloritic rocks have become blackened by metamorphosing influences, it is extremely difficult and often impossible to distinguish one from the other by their physical appearance.

The vein can be followed continuously from its apex in the Argonaut claim to the lowest level of the mine without break or interruption of any kind.

The apex and upper portion of the Argonaut mine is wholly in massive diabase which is found much decomposed for some distance on either side of the vein to a depth of several hundred feet, but for most part retaining its massive structure.

In proximity to the vein an alteration to a splintery or schistose condition may often be observed, and impregnations of pyrite are of frequent occurrence where such alterations are found. In the hanging wall diabase are found numerous small veins and seams of quartz, some of which lie nearly parallel with the principal fissure plane, but the greater number have a westerly dip, extending upward from the fissure into the hanging wall.

Similar seams and vein-like sheets also occur in the foot wall diabase, but usually in lesser number. These attendant sheets and veins of quartz are incidental to many veins elsewhere and very frequently contain sufficient valuable mineral to entitle them to be included in the zone of "pay rock" together with the main fissure when the entire zone of mineralization is, and very properly should be considered as a single vein or lode.

In making an examination of the vein structure and wall rocks in a raise extending upward from the 470-foot level to the adit (Pioneer tunnel) level of the Argonaut mine geological conditions exist which at once determine the fact that the vein occupies a "fault-fissure," the hanging wall having moved upward relatively to the foot wall, constituting a "thrust" or "reverse" fault. There may possibly have been also a lateral movement along the fissure plane to the southward, striations found on the walls of the vein, dipping to the northward, tend to strengthen this belief. The amount of displacement as determined by measurement in the raise is about 125 feet.

VERTICAL CROSS SECTION OF THE VEIN IN THE ARGONAUT MINE.

The quartz occurs along this fault plane in a most persistent manner and is rarely absent, even for a short distance. In width the quartz varies from 1 to 2 inches to upward of 30 feet. When for a brief space quartz disappears in the raises above the 470-foot level, the "gouge," resulting from attrition caused by the movement of these rock planes upon each other, and which always accompanies this vein, clearly indicates the plane of the fissure. In passing through these raises it may be noticed that where no quartz appears in the fissure on one side of the cutting it may usually be found on the opposite side. No more conclusive evidence of a continuous vein than the fact that it occupies a fault plane could be desired.

It may be contended that this vein occupies a contact fissure, but abundant evidence, found on the several levels of the mine, indicates clearly that the contact is of purely local character and that the fissure is absolutely independent of it, for the vein does not conform for any considerable distance, in the Argonaut mine, in either strike or dip, to the contact planes of the black clay slates of the "Mariposa beds" and the diabase, or the schistose and slaty rocks resulting from its alteration.

The dip of the vein varies from a comparatively small angle at the apex to about 67° from the plane of the horizon in the lower levels, and in general at a somewhat lesser angle than that of the inclosing rocks.

W. H. STORMS.

The Pioneer lode location, as patented, includes the apex of a quartz lode, the surface course of which extends through the length of the location, along the center line thereof and parallel with both side lines. This apex is shown on the surface in shallow pits and cuts at the north end line for about 60 feet southward within the Pioneer ground. Its further course southward is covered by a body of conglomerate cement, which forms the capping of this part of the hill. At a point 314 feet from the north end line, and on the center line of the location, a vertical shaft, 71.5 feet deep (commonly called the 60-foot shaft) has been sunk through this conglomerate to the apex of the lode, which is clearly disclosed at the bottom of the shaft. A shallow inclined winze has been sunk on the lode at this point, and a drift has been run on the lode northward for about 32 feet. This drift discloses a continuous lode under the conglomerate capping.

Southward from the said 60-foot shaft the conglomerate extends for several hundred feet, forming a practically level summit ridge, but at a point about 500 feet from the south end line of the Pioneer ground the surface falls away rapidly southward, and the conglomerate capping being no longer present (having been removed doubtless by erosion), the underlying rock is again exposed at the surface, and the apex of the vein is shown in several pits and trenches, which exhibit the vein quartz in place, nearly on the center line of the location. The course of the apex of this lode is thus shown to be along the said center line, notwithstanding the difference in altitude at different parts of this course. An absolutely horizontal line in the vein would show the "true course," in a technical sense, to be more nearly north and south than this actual surface course or apex course. In other words, if the south end of the claim had not been reduced in altitude by erosion, the apex, existing in that case at a higher level, would cross the south end line at a point farther west than the point where it now crosses.

The lode thus disclosed at the surface or under the conglomerate lies between greenstone walls on both sides and dips eastward. It is again encountered at a point about 71 feet vertically lower than the bottom of the 60-foot shaft, and 205 feet farther east, by the so-called Spring tunnel, which cuts the lode 184 feet from the tunnel mouth. From this point an upraise has been started to connect with the apex at or near the bottom of the 60-foot shaft, an inclined distance of 225 feet. This upraise will be somewhat oblique and flatter than the true dip of the vein. It has not yet been finished so as to exhibit a connection on the vein throughout; but an inspection of the map will show that the level of the Spring tunnel is within the ground of the Pioneer location and that it is physically impossible for the lode there revealed to apex outside of the said ground. However, I am entirely satisfied as to the fact, not questioned so far as I am aware by any person, that the lode in the level referred to is the same as the lode shown at the bottom of the 60-foot shaft.

From the intersection at the Spring tunnel this vein is exposed continuously down to the Pioneer or adit level by an upraise showing quartz, gouge and walls. This level has been run in the lode for 812 feet north and 112 feet south, showing a continuous vein. The course of the level is, for the reason given above, more nearly north and south than the surface course of the apex.

From this level down to the 290-foot level of the Argonaut mine the vein is exposed by an upraise between the walls and within the vein. Gouge and quartz and sometimes (but not at all points) the walls can be seen. The walls are greenstone, softened and altered by surface influences to some extent, but clearly recognizable. The dip of the vein continues to be flat—say about 37½°.

A similar upraise between the 490 and the 290 foot levels shows the vein to continue with a dip of 48° to the 470. But about 31 feet below the 290 the greenstone of the hanging wall gives way to the black slates characteristic of the Mother Lode zone. In other words, the lode in its downward course reaches the contact between the greenstone and the slates which overlie it. The contact at this point stands steeply, dipping 69° to the east.

The two rocks are "frozen" together, and there is neither quartz nor gouge in the plane of contact.

From this point down to a point about 38 feet below the 385, and 63 feet above the 470 level, the upraise shows the lode to have a slate hanging wall and a greenstone footwall. In other words, the lode is for this distance and on this particular cross-section "in the contact." At the 470 level it is wholly in the slate, both opposite the shaft, and at the point where the upraise leaves the level. But farther north on the level the greenstone is again seen in the footwall, thus showing that the vein does not everywhere occupy the contact, even on that level. In other words, this lode has no structural relation to the contact, but cuts through it obliquely in both strike and dip. It is a matter of no importance how far the lode is, at any given point on any level, from the contact.

The lode apparently occupies a fault plane, which has cut through greenstone and slates, without regard to their position and relations. There are signs of movement in the walls, such as crushing and contortion of the slates, slickinsides, etc., indicating that the movement was a thrust or reverse fault—that is, that the hanging wall was moved relatively upward. If the direction of this movement had been straight up on the dip, its extent could perhaps be measured by the distance between the point where the faulting lode reaches the contact and the point where it fully enters the slates—say about 123 feet. But I think it more likely that the movement of the hanging wall was obliquely upward—that is, was a southward as well as an upward movement, and its extent was proportionately greater than its upward component of 123 feet, as measured in the upraise.

It is probably impossible at this time to unravel and analyze all the movements which have taken place in these rock masses since they were first consolidated, and it is fortunately unnecessary to do so, since the ultimate result, as left by the final process (whatever it was) is a continuous fissure vein, extending from the apex to the bottom level of the Argonaut mine. Nor is it necessary here to state in detail the proofs of the identity and continuity of this lode from the 470 to the 1350 level. They consist in winzes and upraises exposing the vein and successive levels and stopes upon it, from which thousands of tons have been removed. The character of ore and gouge is maintained, except so far as the nature of the walls modifies it. The heavy black gouge, for instance, is characteristic of the vein in the slates. The walls sometimes show greenstone on the so-called gray slates, which are a schistose variety of greenstone; but these occasional alternations, doubtless due to the cutting of layers of different rock by the vein fissure, do not affect its course or dip.

In the Kennedy mine the same lode is worked to a much greater depth. Its identity is shown wherever the workings of the two mines are connected by continuity of stopes, walls, gouge and quartz. From the 1350 level of the Argonaut to the 2100 level of the Kennedy mine, these proofs of identity and continuity appear.

On the 470 level of the Argonaut and on every level below the workings of the Kennedy Co. have been encountered in driving northward. I consider, therefore, the following to be the facts proved:

1. The Pioneer lode, which is worked in the Argonaut mine, has its apex in the Pioneer location, both end lines of which it crosses.

2. It maintains its identity and continuity from the said apex to the bottom of the lowest level of the Argonaut mine.

3. It is the lode upon which the adjacent workings of the Kennedy Co. have been made, including all the underground workings of said company, which proceed from the South Kennedy shaft and extend southward as far as the boundary formed by a vertical plane drawn through the north end line of the Pioneer location.

R. W. RAYMOND.

That First California Mining Electric Plant.

TO THE EDITOR:—Referring to your statements in "Concentrates," March 4th and 11th, regarding first use of electrical power transmission in California mining, I would say: At the Big Bend mine, Feather river, Cal., an electric plant was installed in '88 and used during that season. The plant consisted of two Edison dynamos, 70 H. P. each, driven by water wheels; one 8-foot Knight and one 4-foot Pelton, under 300 feet head; twelve motors, 5 H. P. each and eight miles of line of four wires. Power was delivered at four camps where mining was being done in bed of river. Eight motors were used to drive as many Richards centrifugal pumps, 4-inch suction and discharge, and the other four to furnish power for derricks used in moving boulders. The wire used on pump circuit was about ⅜-inch diameter and weighed 1600 pounds per mile. Wire on derrick circuit was ¼-inch diameter and weighed about 800 pounds per mile.

A great deal of trouble was experienced on account of motor armatures burning out, a number being removed by the California Electrical Works at a cost of $100 each. Prof. Keith of San Francisco removed one or two late in the fall. The plant was taken out and the wire (52,000 pounds) shipped to New York in January, '89.

Mr. N. A. Harris of 414 Cole street, San Francisco, was Gen. Supt. and myself foreman, until August, '88, when Mr. Harris resigned to take the management of the Golden Gate mine at Oroville, and I was appointed Supt. in which position I remained until the mine was finally closed down.

A. K. BEATSON.

Oakland, Cal., March 14th, '99.

Numerous Rotary Engines.

This class of inventions now averages about three patents per week. There are now on file at Washington nearly 500 rotary patents.

The rotary engine in its perfected state will have seven distinctive advantages already recognized by mechanical authorities over the reciprocating form. They are:

1. Absolute control of the steam power by cut-off and valves.
2. Minimum of space occupied, both for engine and boiler.
3. Minimum of cost of manufacture.
4. Minimum of steam necessary to develop a given amount of power.
5. Minimum of friction and wear, and the avoidance of dead working parts.
6. Interchangeability of its eight simple working parts.
7. Regulation of speed without loss of power or sacrifice of durability.

MOST of the circulars sent to busy men are consigned immediately to the waste basket without so much as a hasty perusal. An Eastern firm, realizing this, prints the following on the envelope: "Caution: Remove the envelope carefully and exercise still greater care in handling the enclosed circular. Don't throw it in the waste paper basket, or give it to the servant to light the fires with, as the most disastrous results will follow, inasmuch as the circular is dipped in a solution of dynamite. Hang it up in a cool, dry place, and after a few days' exposure its dangerous properties will disappear, and it can be burned like any other circular." Then at the lower edge of the envelope is printed: "N. B. Most firms do their heavy lying in their circulars; we alone do all of ours on the envelopes."

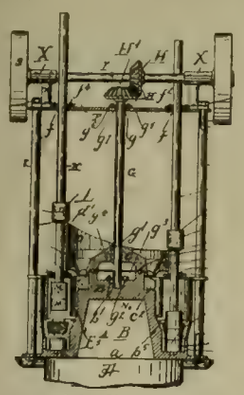
AN electric rock drill is reported in use by a coal company of southern France for tunneling through very hard rock wherein the power of a waterfall several miles away is utilized, and to the axle of the turbine wheel an alternator with a three phase current is attached. The current is made use of in various ways, for it drives the drills, furnishes power to a motor carrying out the debris and actuates the fresh air fans.

Latest Mining and Metallurgical Patents.

Patents Issued March 14, 1899.

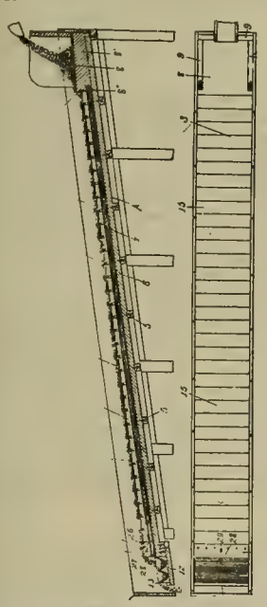
Specially Prepared for the MINING AND SCIENTIFIC PRESS.

ANNULAR STAMP MILL.—No. 620,962; F. L. Pres-, Beloit, Wis.



An annular central-feeding stamp mill; a combina- with a mortar frame provided with an annular chamber, stamps mounted to reciprocate therein an annular ledge or shelf on frame adjacent to upper surface thereof, of a camwheel mounted to ate on the upper surface of mortar frame to op- te stamps; provided with a conical hub and a rality of apertures through which ore may drop on annular ledge, plows mounted on wheel and apted to scrape the ore from ledge to the die cham-, and means for rotating camwheel. The stamps mounted to coact with the dies, provided with rtically extending rotatable stems, a frame unted on mortar adapted to support the guide mp stems, tappet surfaces on stems, a camwheel atively mounted on mortar, the cam surfaces of ich have rolling contact with tappet surfaces; rtures between the periphery of wheel and its for the passage of ore therethrough upon the ular ledge or shelf.

OXIDIZING FURNACE.—No. 620,887; H. J. Clark, ver, Colo.

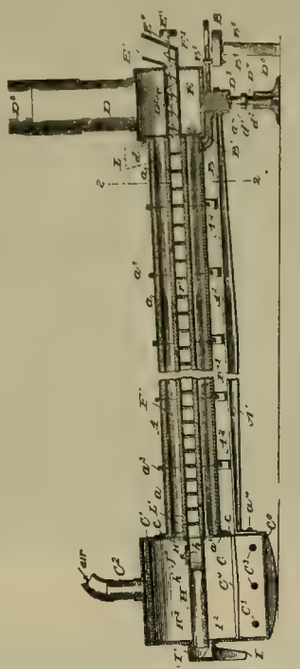


An oxidizing furnace combining an oxidizing flue, ans for oscillating the same, and retarding de- es extending transversely from opposite sides and rtially across flue, of a fire box and smoke box at posite ends thereof, a supporting beam connected fire and smoke boxes, and means upon beam for pporting flue and rotatable bearings for same, an e roasting passage and ore drying passage, means introducing and removing ore from drying pass- e and independent feeding and delivery devices ore roasting passage.

ANODE.—No. 621,121; J. T. Morrow, Great Falls, nt.

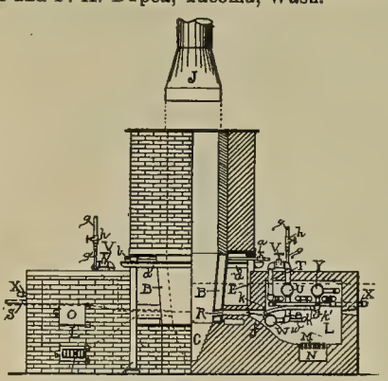
An anode, consisting of impure cast copper and one or more loops of sheet metal, both ends of which are secured in the impure copper by being cast therein.

AMALGAMATOR.—No. 621,092; A. H. Jocelyn, New York, N. Y.



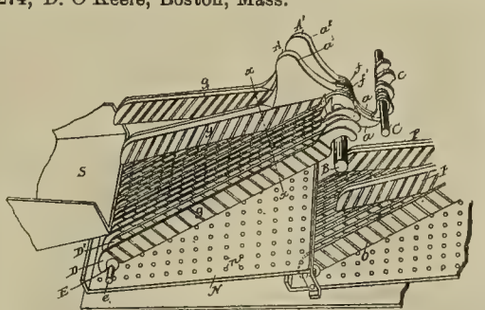
An amalgamating device comprised of a sluice formed of a series of shiftable, freely removable, interchangeable, overlapping and interlocking flat, non-pan-formed amalgamating plates disposed in position to form a stepped surface to permit the free passage of water thereover, all of the plates being simultaneously shiftable on the removal of one or more from the series, and each of a construction and formed of precious metal throughout, whereby it may be melted up with the amalgam attached thereto.

SMELTING STACK FURNACE.—No. 621,088; C. A. House and F. A. Dupea, Tacoma, Wash.



A stack smelting furnace comprising a set of hydrocarbon gas generating and combustion furnaces connected with and located on the sides of a stack furnace, each generating and combustion furnace having a superheating steam-pipe coil and a superheating air-pipe coil fixed in the upper part thereof; the steam-coil having a valve for regulating the steam supplied therethrough, connections for supplying oil to coil, a suitable chamber for receiving and mixing the oil and the superheated steam simultaneously, pipes leading therefrom into a discharging chamber, air-coil having a discharging chamber with discharge outlets opening into a flue passage leading from the generating and combustion furnace into the stack furnace, all to be used in combination therewith and to furnish heat thereto.

MECHANICAL DISINTEGRATION OF ORES.—No. 621,274; D. O'Keefe, Boston, Mass.

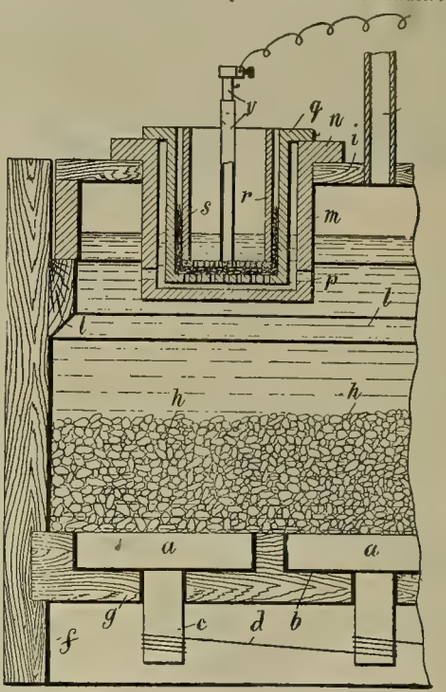


A machine for the mechanical disintegration of ores; a combination of hinged rising and falling beaters, A, A', A², A³, and P, P', P², P³, supported on stationary shafts, B, actuated by cams, *c*, revolved by shaft, C, which is driven by any suitable means; the bars having vertical depending rods, H, which pass through upper member, *k*, of the traverse box girders, K, attached to the frame of the machine carrying disks, *k'*, supporting springs, I, in compression between disks, *k'*, and upper member, *k*, of transverse girders, K, and which are further compressed by this vertical movement of these beaters.

Gold Extraction by Electrolysis.

In connection with electrolysis in utilization for gold extraction a description of a process recently devised for this purpose may be of interest.

The apparatus may, as claimed, be used for the extraction of gold from any auriferous material by direct chlorination and the simultaneous generation of sodium amalgam, or it may be used as a separate generator of chlorine gas and sodium, to be afterwards used in connection with gold extraction or for the electro deposit of gold from solution. As will be seen from an illustration reproduced from *Industries*



and Iron, the electrolytic cell is composed of wood having carbon blocks or plates *a* set in the bottom with bitumen or other suitable non-conducting material. Carbon studs shown at *c* pass out through the bottom and have their extremities copper plated, a conductor marked *d* being connected with them and carried to the terminal. The sides of the cell are carried for convenience below the bottom of the cell shown at *g*. When this form of cell is used for chlorination purposes the carbon plates set in the bottom, as hereinbefore described, form the anode; and if it be used for direct chlorination of material within the cell itself the material *h* to be so treated is placed in the cell with a solution of sodium chloride. The cell has a lid cover *i* resting on supports, and this lid carries the cathode pots *m*, which drop into holes in the lid and rest upon flanges *n*, the said supports which carry the lid being below the water line, so that the lid is sealed and forms a trap for the gases liberated in the cell. The cathode pots are fitted into the lid in such a way that by their flanges the lid is sealed, and forms a trap for the gases liberated in the cell, this being obtained by rubber packing, clay luting, or other convenient means. The lid is fitted with a tube *o*, which may be placed in any convenient position, and by means of which the liberated gases, such a chlorine, may be carried off.

The cathode pots are constructed of porcelain or other suitable material, and are made in three parts, comprising an outer pot *m*, perforated all round a little above the bottom with holes, *p*, an inner pot *q*, having its bottom perforated all over with holes, and a plain cylindrical sleeve *r* over the bottom, of which a piece of linen, canvas or other suitable fibrous material, shown at *s*, is stretched before it is inserted in the inner pot, marked *q*. These three pots when put together with a suitable piece of linen or canvas form a porous pot, having very little electrical resistance and suitable for use with a mercury cathode. The fabric *s* preferably extends beyond the edges of the sleeve *r* and fills part of the space between the sleeve and the inner pot. Mercury to the desired depth is placed on the fabric on the perforated bottom of the pot, and any mercury or amalgam dripping through falls into the bottom of the outer pot *m*, and is retained therein owing to the perforations being situated some distance above the level of its bottom.

The Genesis of Petroleum and Asphaltum in California.

NUMBER VIII.

Written for the MINING AND SCIENTIFIC PRESS by A. S. COOPER.

At the time of their deposition in sea water and before any alteration had taken place the red shales should contain chloride of calcium, carbonate of calcium, carbonate of iron, carbonate of magnesia, sulphate of calcium, etc., vegetable matter in a fine state of subdivision, and in some places large deposits of vegetable matter; this organic matter in time becoming carbonaceous shales and seams of coal. When these shales are heated with a chemical heat the following described vapors and gases are given off: sulphur dioxide, carbonic acid, sulphuretted hydrogen, carburetted hydrogen, distilled from the carbonaceous substances, nitrogen derived from the same source, etc. These vapors are forced into the circumjacent formation which are highly charged with mineral matter originally present in the shale and which had been deposited from hot water. Chemical actions arise when these vapors or their condensations come in contact with the minerals existing in the shales causing heat. There remains in the shales, after the vapors and gases are eliminated by heat, oxide of calcium, oxide of iron, etc. Mineral waters and gases coming in contact with these substances produce heat. These chemical actions and reactions are complex and numerous. By these chemical actions and reactions, distillations and condensations the alteration of the shale by heat becomes progressive and cyclic. This heat, under great pressure and through subsidences and orogenic movements, is intensified. Chemical reactions are augmented through pressure and hydrothermal action. The hydrocarbons and other substances are distilled and condensed, dissociated and united a multiplicity of times. Mineral springs, ranging in temperature from that of the earth from which they issue to the boiling point, are frequent in the neighborhood of these burnt shales. They contain in notable quantities sulphate of sodium, magnesium, calcium, aluminum, carbonate of sodium, calcium and magnesium, chloride of sodium, potassium and calcium, silica, and, in excess, carbonic acid, sulphuretted hydrogen, carburetted hydrogen and traces of arsenic, sulphuric acid and iron. Besides the visible phenomena, the warmth of these springs shows that this metamorphic action is still in progress.

Deposits of bitumen in California are found in sedimentary rocks of all ages, and principally in three different ways: 1. In superficial detritus. 2. In veins. 3. In porous or seamed strata. The bitumen may be of any consistency, gaseous, fluid, viscous or solid.

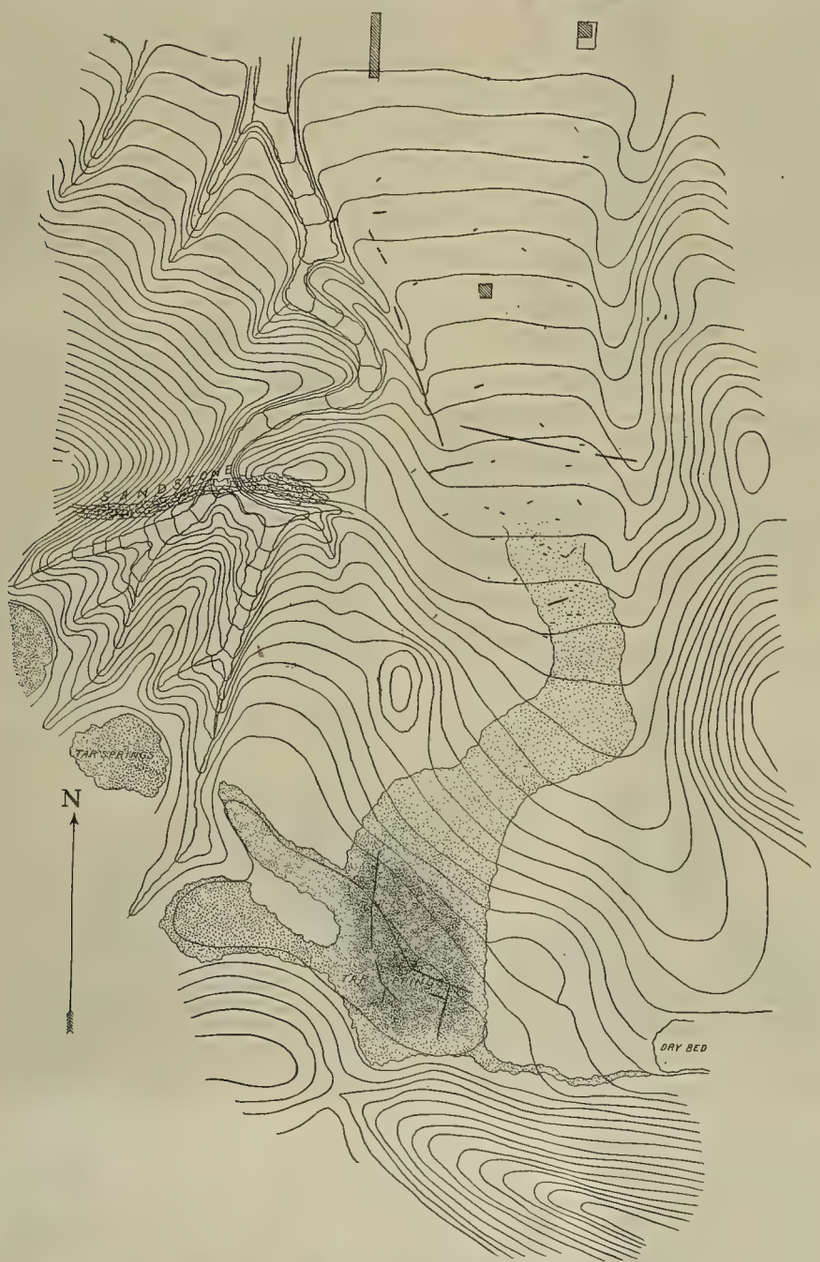
Bitumen often occurs in superficial detritus or alluvium. This character of deposit is usually the overflow of tar springs, into which the detritus from the surrounding country has been washed or blown, and in case where mineral tar is sufficiently liquid it has percolated into the underlying earth. The detritus when saturated with mineral tar most always has been repeatedly burned, leaving black vesicular clinkers, which are frequently refilled where there has been a flow of tar after the fire.

Cooking utensils of the Indians are found in the vicinity of these tar springs, showing that they were used for purposes of fuel. After this they were set on fire by shepherds, so that the fleeces of their sheep would not be injured or lambs suffocated by going into the sticky mass. Where the bituminized detritus has escaped the fires and exist below the clinkers, it contains about 5% of brown and friable bitumen, having a specific gravity less than water. It consists of 70% of asphaltene and 30% of petrolene. The accompanying map section and view show the Buena Vista oil spring at Asphalto, Kern Co., Cal. The mineral tar reaches the surface at the place marked tar spring. At the place marked tar springs a number of trenches have been cut, and a tank erected so as to intercept and save the tar. These trenches are cut in clinkers and comminut shale, which is often saturated with tar. Thin l ers of detritus impregnated with mineral tar lyi nearly horizontal are intercalated with thicker l ers of detritus which contain no bitumen. The beds are formed by flows from the tar springs a deposition of detritus denuded from the adjoini hills. Before this deposit was worked mineral t had flowed from the springs over the surface of t clinkers, until it had reached a thickness of fron to 6 inches; it had evaporated and oxidized, beco ing stiff. It was of different degrees of purit sometimes absolutely pure; at other times it co tained as high as 80% of detritus. In 1891 and 18 this concreted tar was being mined and refined. the present time there are but a few tons, which a scattered over the ground in small pieces. It h been estimated that in recent years these sprin afforded about 160 barrels annually. There are large number of other tar springs in Californ nearly all of which have been burned in the mann described above.

In the shaft sunk at the Hancock deposit, lyi northwest of the city of Los Angeles, in the center what appeared to be an old tar spring, on the surfa were found the bones of domestic animals—horse cattle, sheep, etc.; at a greater depth the bones the bear, elk and other wild animals, and resting the shale beneath the bituminized sand, at a dep of about 30 feet, were the bones of the *Elephas Am icanus*. During the latter part of the summer se son in California the natural grasses dry up, b owing to the slight amount of water which ascen with the bitumen, as it does at the present time, ma years ago, during the dry season, there grew, su rounding these asphalt springs, green and succule herbage. This herbage was the bait of the tr which tempted these herbivorous animals to the death. With everything else dry, these green her were an irresistible temptation. In struggling get to them the animals became mired in the t lake and suffocated, their bones gradually sinking the bottom.

The *Elephas Americanus* seemed to be the first o that met this fate, as his bones rest upon the unde lying shale, below the remainder of the fossil These springs must be very old, as it is many yea since the American elephant fed upon the plai adjacent to the spring.

(To be Continued.)



BUENA VISTA OIL SPRING, ASPHALTO, KERN COUNTY, CAL.

Telluride Ores.

There is much interest now in telluride ores, as is becoming known that they occur much more com monly than was supposed. Important localities ar Cripple Creek and other mining districts of Col rado, the northern Black Hills of South Dakota, an several counties in California. Following is a de scription of several of the most important gold an silver tellurides, from Dana's Mineralogy:

Altaite—Lead telluride, usually massive with cubi cleavage; color, tin white with yellowish tinge tar nishing to bronze yellow.

Naumanite—Silver-lead telluride, in cubic cry tals; also massive, granular and in thin plates cleavage cubic; color and streak iron black.

Hessite—Silver telluride, usually massive, com pact, or fine grained; cleavage distinct and usuall somewhat sectile; color batween lead gray and stee gray. This species also often contains gold, an graduates toward petzite.

Petzite—Massive; granular to compact; slightl sectile to brittle; color steel gray to iron black; tar nishing.

Sylvanite—Telluride of gold and silver; often i branching arborescent forms resembling writte characters; also bladed, and imperfectly columna to granular; cleavage perfect; fracture uneven hardness 1.5 to 2; brittle; luster metallic, brilliant color and streak pure steel gray to silver white, in clining to yellow. Comp.: tellurium 62.1, gold 24.5 silver 13.4.

Calaverite—Gold and silver telluride, much lik sylvanite but contains more gold; massive; hard ness 2.5; color pale bronze yellow. When crystal lized it is known as kennerite.

Nagyagite—A sulpho-telluride of lead and gold containing also 7% of antimony; in tabular crystals also granular, massive and foliated; cleavage per fect; flexible; hardness 1 to 1.5; luster metallic splendent; streak and color blackish lead gray.

Tellurium—In prismatic crystals; commonly col umnar to fine granular; massive; color tin white contains no gold or silver.

Tellurides heated in the open tube give a white or grayish sublimate which is fusible to colorless drops. On charcoal gives a white coating and colors the flame green.

In some instances telluride ores rich in gold are so finely disseminated in the gangue as to make identification by physical appearance impossible.

EACH letter is not of equal importance in the formation of words. The relative proportions re quired in the English language are these: a, 85; b 16; c, 30; d, 44; e, 120; f, 25; g, 17; h, 64; i, 80; j, 4 k, 8; l, 40; m, 30; n, 80; o, 80; p, 17; q, 5; r, 62; s, 80 t, 90; u, 34; v, 12; w, 20; x, 4; y, 20; z, 2.

The Alluvial Deposits of Western Australia.*

NUMBER IV.

By T. A. RICKARD, State Geologist, Denver, Colorado.

The cement deposit occupies a very shallow depression, and in its structure bears internal evidence of considerable geological age, suggesting that it was formed at a time when the Sugar Loaf reefs reached the surface at a level superior to the slight ridge now separating them.

Another deposit of similar character has been explored at Kanowna, twenty-five miles northeast of Kalgoorlie, and about sixty miles east of the locality just described.

The discovery was made in '93. Each digger secured a claim 50 feet square and sunk a shaft to the gold-bearing cement which the dry blowers had uncovered in the course of their prospecting. The deposit became in due time "gophered" with holes and shafts, so that the boundaries of the cement were accurately determined. In '95 an English company secured the property and consolidated the claims into larger leases. The expectations held out freely by responsible engineers that an extremely profitable enterprise could be based on the remnants of gold-bearing ground were wholly dissipated in the succeeding two years, a gross blunder having been made simply through insufficient and unsystematic sampling.

The deposit lies in a shallow trough, the longer lying axis east and west. The body of gold-bearing cement has a length of about 700 feet and a maximum width of 105 feet. Vertical sections exhibit an overburden of sandy loam, from a few inches to 2½ feet thick. This was the material worked by the dry blowers. Then comes a layer of detritus, called "wash" by the miners, composed of fragments of ironstone and quartz imbedded in clay, and reaching to a maximum of 25 feet from the surface. This overlies the cement itself 6 inches to 5 feet thick, and is easily distinguished from its roof of detritus and its floor of clay. The cement consists of particles of quartz in a greenish clay. Near the rim of the trough the quartz occurs in larger and more angular pieces. A typical

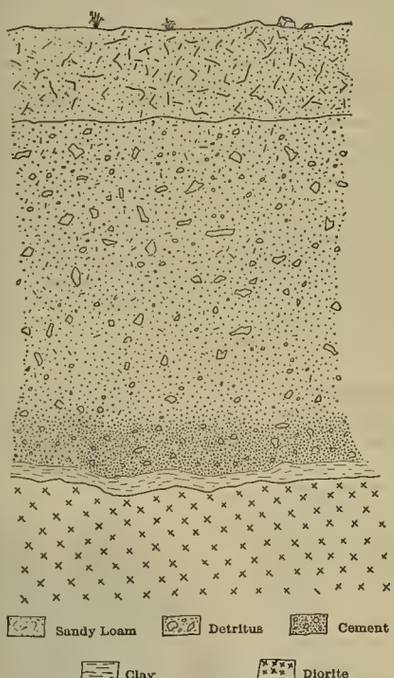


FIG. 15.—TYPICAL SECTION OF KANOWA.

section, obtained from a pillar in the old workings, is given in Fig. 15.

The gold contents are irregular. The whole body of cement probably averaged one ounce per ton; but only the richest parts were worked, and these carried many ounces to the ton; so that the remnants now accessible average, from the surface down, about 3½ dwts. The clay carries 2 dwts. per ton. The material was treated at neighboring stamp mills.

When the neighboring mines, the White Feather Reward and the White Feather Main Reef, were visited, it seemed as natural to deduce this cement deposit from the erosion of gold-bearing quartz veins as it had been to relate the Sugar Loaf reefs at Kintore with the deposit worked by the West Australian Proprietary Cement Co. Further investigation confirmed this inference.

The McAuliffe vein (worked by the W. F. Reward mine) and the Main Reef (worked by the W. F. Main Reef mine) traverse diorite at or near the line where large dikes of porphyry penetrate. The two reefs are probably identical, and have a strike which takes

DRY BLOWERS AT WORK.

them right across the longer axis of the cement deposit at a point near the head of the trough in which it lies. A shaft recently sunk to a depth of 200 feet by the Golden Cement Co. reached this reef by means of a crosscut and found a comparatively barren quartz vein, carrying small spots of rich ore. The enclosing rock was diorite, and the quartz itself was encased on both sides by bands of clay fully 2 feet thick.

On comparing the veins and their encasing rocks, as seen in the workings of the two mines on opposite sides of the alluvial deposits, it is not found necessary to go further for the origin of the latter. The cement is underlain by a clay which is essentially steatite, and is as readily traceable to the neighboring diorite as the kaolin at Kintore was deducible from the granite. The green color of the cement is imparted by chlorite, derived from the decomposition of the epidote in the diorite. The "ironstone" of the detritus overlying the gold-bearing part of the deposit consists of fragments of altered diorite. The quartz in the cement and the gold accompanying it are both identical with those of the reefs close by.

Here also the topography confirms the suggested explanation. The cement lies in a shallow depression, at the upper rim of which the quartz reefs cross the country. Furthermore, these reefs traverse a low divide, which in a rough way separates the deposit from another, which slopes in the opposite direction. The latter is known as the Fitzroy cement. In this deposit rich discoveries were made during

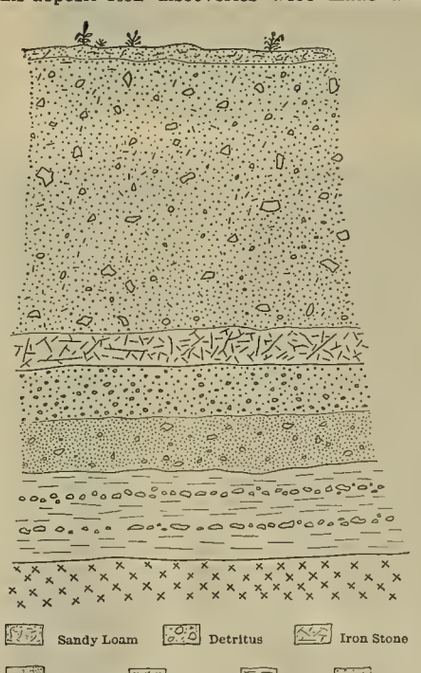

FIG. 16.—SECTION IN FITZROY CEMENT.

October, '97. A typical section is exhibited in Fig. 16.

Apart from their importance as depositories of gold, the cements have played an interesting part in the development of the gold fields, because they often cover the tops of reefs. This feature proved a serious hindrance to the recognition of the lodes at Kalgoorlie, where worthless quartz veins were worked for some time before a trench traversing the cap of the cement accidentally uncovered the top of one of the rich deposits of telluride ore, which did not outcrop, on account of the comparative softness of the lode.

Theories of Origin.—Of course, several theories have been mooted, the most fanciful of which have naturally been those of the working miner himself. The fact that the gold-bearing cement is in places overlain by a considerable thickness of partially consolidated rock has led to the supposition that the deposit was a "deep lead," while the resemblance to a conglomerate has caused more than one Africander to liken it to the "banket" of the Transvaal.

The latter is an immense shore deposit of gold-bearing conglomerates, now covered by a series of later sediments. Its dimensions, comparative homogeneity and persistence are in striking contrast to the narrow, restricted, irregular patches of detritus which have been described as occurring in West Australia. This total unlikeness renders unnecessary any discussion of a fancied similarity of origin.

But because this alluvium disappears under an overburden of rock, the Australian digger fancies he is working a deposit similar to the "deep leads" with which he became familiar at Ballarat, for example. A distinguished government geologist from a neighboring colony visited Kanowna in October, '97, and gave authority to the term "deep lead" by using it himself. "Deep" it may be, for that is a comparative adjective, but a "deep lead" in the technical sense it most assuredly is not. On the Forest Hill divide, in Placer county, Cal., and at Creswick, in the Ballarat district, Victoria, the typical "deep leads" occur. They are, as is well known, old (Miocene) gold-bearing river channels, which have been saved from erosion by a cap of lava. The lava probably overflowed the original surface as a steaming mud, and is now found consolidated into a volcanic rock sufficiently hard to need little timbering when penetrated by underground workings. The cement deposits of West Australia occur under an overburden of "made ground"—that is to say, both the deposit itself and all the material under which it dips are of distinctively detrital origin, the products of weathering and erosion accumulated in shallow depressions of the much-decomposed surface of granite or diorite.

It is the placer of a country destitute of running water. The climatic conditions and the physiography of the Coolgardie gold fields have been carefully described, in order to make it evident why these deposits differ from those of more favored countries, like California or New Zealand. Surely it is not in keeping with the scientific method to seek for fantastic or far-fetched explanations, when processes in operation to-day are able to supply an adequate understanding of the observed facts.

The quartz of the cement is subangular; it has evidently undergone very little attrition, and suggests, therefore, that it has not traveled far. On comparing it with the matrix of neighboring veins, an identity appears obvious. The examination of the topography renders highly probable the derivation of the one from the other. The cementing material is similarly found to be the clay resulting from the decomposition of the rock encasing the quartz veins, and varying according to the composition of that rock, whether it be granite or diorite. Finally, the

* Condensed from paper read before the Am. Inst. M. E.

gold particles which have rendered the cement worth mining are found to be identical in fineness and physical appearance with the gold of the neighboring veins, and their scarcely rounded edges invite the conclusion that the gold also has not been borne far from the place of its origin. The comparatively unclassified condition of the deposits is in keeping with the evidence afforded by the material of which they are composed. The absence of running water on this desert plateau has prevented any such sifting process as in other regions leads to the deposition of well defined layers of clay, gravel and gold upon a clean bedrock. It is an exceptional illustration of the working of those agencies to whose unceasing play is due the configuration of the earth's surface; it is geological action in its most instructive form.

Water Supply.—The early history of the gold fields of West Australia is the record of a struggle to exist amid conditions which were inimical to human life on account of the scarcity of water. That great necessity has been, in some sort, satisfied by the energetic action of the government, supplemented by private enterprise. The gold fields are now dotted over with condensing plants, which turn the brine of the wells into water fitted for the use of man and beast. Existence is thus rendered endurable; but the mining industry is still handicapped by an item of cost unknown in more favored regions.

The water of the country is salt, sometimes almost to the point of saturation. Sea water contains 3½% of salts, three-quarters of this percentage being common salt, the chloride of sodium. At Menzies, in September, '97, I found one of the two important mines of that district using water which contained 17% of salts, and the manager informed me that in December evaporation increased the amount to 30%. For this liquid he paid 25 shillings per 1000 gallons. It came from a neighboring "soak." The condensed (distilled) water, bought for use in the boilers, cost £1 per 100 gallons. Milling in a 10-stamp mill was carried on at an average cost of 30 shillings, or $6 per ton, the item of water alone amounting to 13 shillings, or $3.25 per ton.

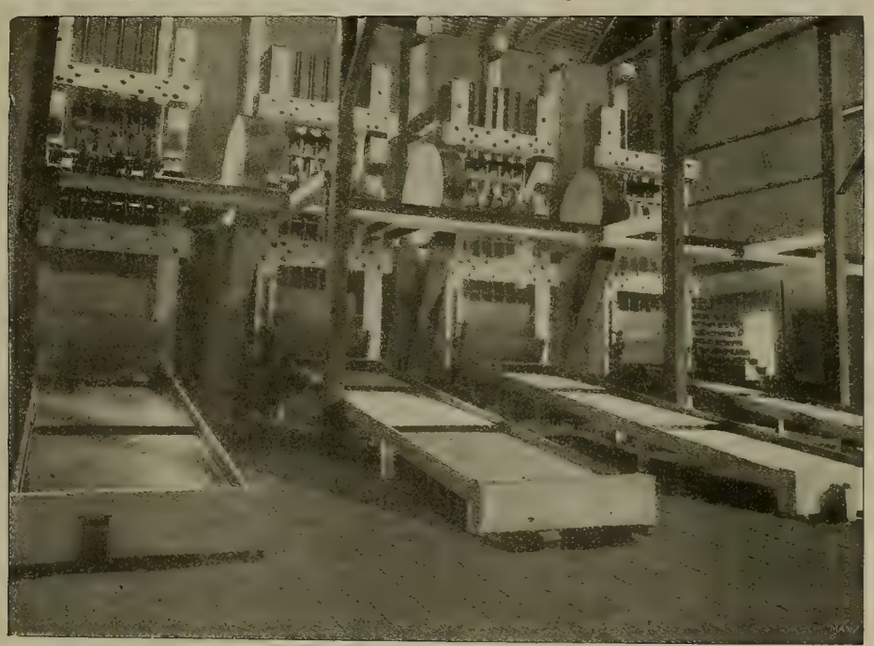
Under these conditions a wet mine becomes a source of revenue. Many properties at Kalgoorlie, unable to find pay ore, lessened the expenses of development by selling their water to those that had mills. The price varied according to the season. At the Great Boulder Main Reef mine, for example, the lowest price paid for water during '97 was £3 10s per 1000 gallons, and the highest £11 5s. This was piped from neighboring shafts, and had not passed through the condenser; it therefore had the character of sea water, but it was four times as saline.

(To be Continued.)

THE quantity of water used in California hydraulic mining at the height of its career was enormous. An estimate made of the amount used and discharged into seven different streams amounted to more than 10,000,000 miner's inches daily and the material of the gravel banks removed by this water was estimated at nearly 40,000,000 cubic yards.

Two Recent Stamp Mills.

On this page are illustrated two stamp mills equipped with Fraser & Chalmers machinery. One shows a 10-stamp mill built for the Athabasca Co., B. C., a graphic illustration of a modern, up-to-date mill interior. The screen plates are removed so that the stamp shoes may be seen. The other cut shows a 20-stamp mill for the Alameda mine in California. This mill has heavy cast iron base plates on concrete foundations, the same as 520 stamps furnished Alaska-Treadwell and allied companies, and is another example of an improved and modern milling plant. The features of the Fraser & Chalmers battery with such details as Blanton self-tightening cams and other labor-saving devices are already familiar to most mill men, but these pictures of mill interiors will be of interest to many.



TWENTY-STAMP MILL, ALAMEDA MINE, CALIFORNIA.

ATHABASCA MILL, NELSON, B. C.

Joint Location of Placer Ground.

TO THE EDITOR:—If eight people want to locate twenty acres each of placer land, and act conjointly so as to make one joint location of 160 acres, can some one of the party locate the eight claims in their names, and can one of the party, as power of attorney for the others, transfer the 160 acres as a whole to another person or company? Is there a published blank for a joint placer location? Must the eight form a co-partnership in order to locate and hold the joint location? Must the locations conform to the surveyed lines, or can not the locator determine by his own selection what he wants, if he marks his boundaries properly?

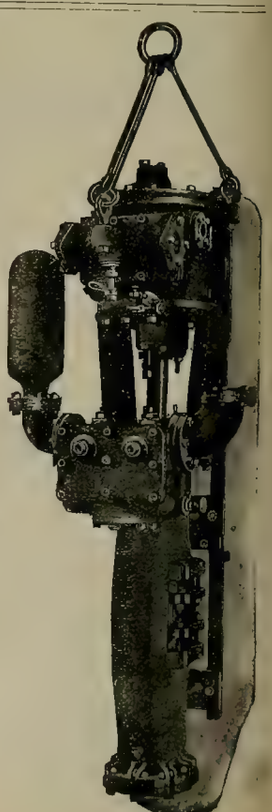
San Francisco, March 20th, '99.

The law permits a single person to take as many placer claims of twenty acres (no more) each as he may desire, and they may be contiguous or not, but requires a separate discovery for each separate twenty-acre tract. Where more than one person (not exceeding eight) participates, an area equivalent to twenty acres for each is permitted, but they locate the area jointly and are not required to locate each particular twenty-acre tract, becoming tenants in common of the entire area. Placer ground so taken also requires a separate discovery for each twenty-acre tract of the 160 acres. A single member of the party may act as agent for each of the others and locate each of the several tracts. If several persons locate contiguous claims in common, such act would in itself constitute co-partnership, and the proceeds of such operation should be equally divided, unless stipulations to the contrary were entered into by all the members of the party holding such claims jointly. Where the land has been legally subdivided, tracts of forty acres may be subdivided into ten-acre tracts; but where no legal subdivision of the public lands has been made, claims may be located with reference to the stream or bank along which the placers occur. Any one member of such association may, if legally constituted an attorney-in-fact, transfer the property to another individual or company. There are no regular blank forms such as you desire.

EIGHT exposition projects are under way in American cities and two more are contemplated; 1899, Omaha; 1899, Philadelphia; 1901, Detroit; 1901, Buffalo; 1901, San Francisco; 1902, Toledo; 1903, St. Louis; 1903, New Orleans. Omaha will hold a "colonial" exposition, Philadelphia an "industrial" exposition, Detroit celebrates its second centennial of discovery, Buffalo calls its show the "Pan-American," San Francisco has decided on "Pacific Ocean and International Exposition," Toledo's show marks the centennial of the admission of Ohio into the Union, and St. Louis and New Orleans commemorate the Louisiana purchase. As expositions in the international aspect they have each other and the Paris and Glasgow world's fairs to compete with or imitate. The Paris exposition in 1900 does not conflict with any dates so far chosen, although Omaha, if again successful, doubtless will repeat in 1900. The Glasgow exposition is set for 1901. Besides those enumerated, a twentieth century exposition for New York city in 1901 is being discussed, without much probability of realization, and a northwestern international exposition in 1902 for St. Paul and Minneapolis has been proposed.

Jeanesville Improved Mine Sinking Pump.

Herewith is illustrated the Jeanesville improved mine sinking pump for sinking shaft, or recovering mines, or for use where a varying water level must be accommodated. The plunger is in one piece, outside packed, particularly adapted for gritty water. The water valves are rubber, with heavy bronze cover and springs. The valve seats are also bronze, driven in the is decks on a taper. The water valve chest cover provided with priming valves, arranged to prime the lower valves from the column pipe, to protect the pump from losing suction while sinking, pumping water and air. The stems are so close that they are in no danger of being broken off. The lower cap under the plunger is held in place by hinged bolts. The whole pump is made up very heavy, to stand hard usage. Material and workmanship are first-class in every particular and are guaranteed. Manufactured by the Jeanesville Iron Works Co., Jeanesville, Pa. Stock carried in their Western branch store, 1328 Seventeenth street, Denver, Colo., A. Middlebrook, manager.



Mining Summary.

ALASKA.

Between Aug. 1st and Nov. 15th, '98, upwards of 15,000 claims were located and staked in the Atlin country, 95% of the locations being made by American miners. It was a new district, but gave promise of rivaling the Klondike in richness. The rush was so sudden and so great that, though the Canadians immediately had a mining recorder and a gold commissioner on the ground, the officials had no books or blanks with which to conduct business, and were unprepared to meet the occasion. A few of the first locators succeeded in getting their claims recorded, the others being merely given a written leave of absence, "until June 1st, '99, on account of inclement weather."

The Exclusion act will deprive Americans from participating in the benefits derived from discoveries made by them. No trouble is anticipated. They will cross over into American territory and prospect for gold in a land where what they find will not be taken from them The Exclusion act will do a great deal for American territory.

The latest Northern steamer reaffirms the former statement from Sitka that the Pande Basin mines have been sold for $2,650,000. The payment of this big amount is to be made quarterly in sums of $132,500 until the entire amount has been cancelled. The Pande Basin property is on Baranoff island, where a lake was drained, and work is to begin upon the receipt of machinery. P. Voorhees of New York is the reputed purchaser. The deal is the largest ever reported from Alaska.

Captain Abercrombie and party will arrive in San Francisco from Washington next Wednesday, en route to the Copper River country. Captain Glenn and party, who are to explore Cook's inlet, left Washington, D. C., on the 23d inst. The War Department has named three stations on the Copper river all-American route to the Klondike country in Alaska—Howard, Tetling and Slahna—to be occupied by United States troops under similar duty to that performed by the Canadian mounted police.

Land travelers have mostly abandoned the road through Chilcoot Pass and they now go through the White Pass from Juneau to Dawson. The distance by land is about 700 miles, while the water route via St. Michaels, on the Yukon, winds around for over 5000 miles.

There are said to be more than 40,000 people at Dawson City.

Miners recently from Copper river, Alaska say that Governor Brady has been requested to ask the Government to send a vessel to Copper river to bring home stranded prospectors. There are nearly 300 people who are without means to secure transportation, and many of them are suffering from scurvy.

A report comes from Dawson that a mammoth has been discovered in a claim on Dominion creek.

Victoria *Times*: There is some excitement at Independence creek, 300 miles below Circle City. This, like El Dorado creek, had been tried by prospectors and pronounced no good, but lately a newcomer had found dirt which gave $7 to the pan, and when the news got out a stampede to Independence creek set in. Men rushed from all points, the stampede resembling that which occurred three years ago to Bonanza and El Dorado in the Klondike.

ARIZONA.

On March 1st the Arizona Copper Co. at Clifton and the Detroit Copper Co. at Morenci advanced the wages of all employes 10%, thus restoring the scale of prices prevailing previous to the cut made in '91. This raise includes everybody employed by these companies, from the superintendents down to the Mexicans who shovel dirt on the surface, and also includes all employes of the Arizona & New Mexico railroad.

J. Lawler of Prescott has bonded his copper properties, five miles south of the Hillside mine and fifty-five miles west of Prescott, to Capt. DeLamar of Nevada. The mines have considerable development and show large amounts of copper ores; $20,000 has been paid on the bond. The price is not made public.

The Tucson *Citizen* declares that assays of ore from the new vertical shaft at the Vulturs mine show the average values of the 27-foot vein opened up in the new shaft at a depth of 212 feet to be: gold, $39.06; silver, $1.89; total, $40.95.

Mohave County *Miner*: J. T. Pendergast, who holds a bond on the Diamond Joe mine, is shipping ore to the Kingman sampler.——C. E. Sherman of Mineral Park has opened up a stope of 600 ounces silver ore in the Katie mine.

Mojave *Miner*: A 50-stamp mill is said to be the next step in improvement at Evan's Point, near Clifton. The recent strike in one of the mines of the company is thought to justify this expenditure.——A body of ruby silver ore has been found in the Merrimac mine at Chloride.——Brown Bros. are shipping ore from their mine on Sherman's peak, near Mineral Park.

CALIFORNIA.

Amador.

A rich strike has been made in the Central Eureka mine, near Sutter Creek. The mine joins the South Eureka on the north and the Old Eureka (Haywards), formerly known as the Con. Amador, on the south. Several years ago considerable ore was taken from each of two ore shoots. The mine was abandoned by the early operators at a depth of 700 feet. The strike was made in the shaft below the 1100 level, a contract to sink 300 feet having been let recently by Supt. W. R. Thomas.

The Old Eureka mine was abandoned at 2450 feet, the immediate cause, it is said, being due to a disastrous fire which caused the mine to cave. It is credited with having produced $2,000,000, and this strike in the Central Eureka may lead to important results.

The Defender mine near Volcano is reported to Eastern capitalists.

Amador *Dispatch*: A strike is reported to have been made at the Bruner mine, two miles south of Angels. The ledge is 8 feet wide.

Dispatch: At the Baliol mine in Sutter Supt. Porter is sinking the shaft and opening up the 300 level. The mill is running, twenty stamps dropping, water power being insufficient to run forty stamps.——At the Zella mine the shaft is being repaired and drifting prosecuted in new ground. The mill is kept running, a portion of the stamps dropping, repairs to the shaft interfering with the hoisting of ore.

Republican: The working force at the Zella, at Jackson, has been increased. Most of the ore is coming from the 1100 level.——It is rumored the Alma, at Jackson, will resume operations.——Work at the Amelia group, adjoining the Argonaut, a mile north of Jackson, has been discontinued, it is said temporarily.

Angels *Echo*: A rich body of ore has been discovered in the Demorest mine, six miles south of San Andreas, within the past few days.——Arrangements have been made to reopen the Angels mine, after an idleness of eight years. This mine will give employment to seventy-five men. The machinery will be run by electrical power, to be furnished by the California Exploration Limited.

Butte.

Oroville *Mercury*: The Oroville Water Co., which purchased the Miocene and other ditch systems, has extensively repaired and enlarged them, and 3500 miners' inches of water are now flowing through the system for use by mines, power plants and for irrigation.

Calaveras.

(Special Correspondence). — The McQuigg mine, a mile north or Murphys, is different from most mines of the district in that the vein is in a fissure crossing the black slate formation at a right angle. The fissure is also a fault plane, the throw being 55 feet, as demonstrated by an older quartz vein which runs with the slates. The mine is opened through tunnels driven on the vein and has a 5-stamp mill. The ore carries considerable iron, lead and zinc sulphides.

Murphys, March 20th, '99.

Chile gulch is filled above its former level to a depth of 40 to 60 feet with the tailings of the early hydraulic mines, all of which contains gold.

The new Ford mill at San Andreas is working smoothly and gives satisfaction. Its capacity is sixty tons per day. This is a large tonnage, but the character of the rock permits it. Perforated tin screens are used. The gold is coarse. The mine is developed to the 700 level through a two-compartment inclined shaft. There are levels opened at 300, 400 and 700 feet. Taken as a whole the mine is low-grade, but there are places where quartz seams a fraction of an inch to 4 inches wide cut the slates which are rich in free gold and the variety of telluride ore known as petzite. The battery is supplied with water from the mine. The mine lies in the zone of amphibolite schist east of the main "mother lode," but approximately parallel with it.

Chronicle: The Petticoat M. Co. at Railroad Flat has leased the Loftus mill and will crush ore at once. The company has out 3000 tons of ore. The rock will have to be hauled one mile. C. W. Laidsay is Supt.——The reservoir at the Green Mountain hydraulic in Chile gulch broke recently, and the rush of water carried away about 100 feet of flume. Operations were suspended to repair damages.

Del Norte.

Record: H. Nicholas is working placers on Mill creek with success.

El Dorado.

Placerville *Democrat*: Wm. Craddock has his shaft down 70 feet and will start his stamp mill.

Inyo.

The Electric Gold Extraction Co., with its object the extraction of gold from ore, headquarters at Bishop, has filed incorporation papers. W. W. Waterson, J. C. Unthank, P. Somerville, P. P. Keough, T. E. Leece.

Kern.

The supervisors of Kern and San Bernardino counties are considering the advisability of making a survey to establish the line dividing the two counties. Randsburg is close to the line and a new survey may make important changes.

Randsburg *Miner*: At the Trilby mine twenty-two men furnish 130 tons of ore daily to the Yellow Aster mill. The Trilby and Rand tunnels, 114 feet feet apart, have been connected. The shaft is being sunk to the level of the Hercules tunnel.——It is rumored the Little Butte Co. has a bond and lease on the Butte mine for ninety days.——Work is being pushed on the new gravel diggings and twenty tons more will be worked at the Red Dog mill in Johannesburg. The car milled last week at Barstow gave satisfactory results. A number of men are at work, but the dry washing process is held back on account of the rain and snow.——M. P. Minor made a test of nine and one-quarter tons of Golden Glame ore at the Red Dog mill, Johannesburg, which gave $25 per ton. The ore was taken from several veins. Mica schist and decomposed granite, which showed hornings were put into the test.

Los Angeles.

(Special Correspondence).—There is an extensive placer field in western and northern Los Angeles county, in the region of Soledad canyon and its tributaries, and extending to the Santa Clara river and its tributaries. The gold is found in the beds of the streams and on high bars along these streams and in the region near Newhall. On both sides of the Southern Pacific Railway gravel deposits are found wherever erosion has not removed them. The entire country, consisting of rolling brush-covered hills, is covered with gravel containing gold. These gravels exhibit some curious features. The material composing them is largely foreign, consisting mostly of rhyolite pebbles and cobbles and other hard rocks not found in the vicinity. The surface of these deposits is usually richer than the underlying portions, due, probably, to the removal of a portion of the material constituting the upper portion of the stratum by winds and rain. These agencies being unable to move the gold, the deposit became enriched. Clay appears at a depth of 1 to 2 feet, solidly cementing the gravel into a species of "hardpan," and beneath this little gold is found. The origin of the gold in these deposits may possibly be traced to the large beds of conglomerate which lie along the upper Soledad canyon near Lang's station and about Ravenna. The material composing these conglomerates also forms a large portion of the gravels, and it seems quite reasonable to look to the conglomerate as a source of the gold, though originally derived from veins elsewhere. The placers in and tributary to San Francisquito, Texas, and Dead Man's canyons probably derived their gold mostly from the large number of small veins in the neighboring hills.

Los Angeles, March 20th, '99.

Madera.

(Special Correspondence).—One of the largest gold-bearing veins in the State extends from the vicinity of Grub Gulch southward across Fresno river and beyond, a distance of nearly 15,000 feet. It is located throughout its entire length, and has at various points a large amount of development, particularly in the Mammoth, Starlight-Riverside and Savannah mines. The formation is mica slate, and the vein occurs as a silification of this slate. A vein of granite of varying texture accompanies the vein throughout its length, waving back and forth in a sinuous line cutting the vein at a number of points, always appearing as of later origin.

Grub Gulch, March 20th, '99.

Marin.

An unconfirmed report from Bolinas asserts that the Golden Crown copper mine has been sold to Philadelphia men for $150,000.

Mariposa.

(Special Correspondence). — The Golden Crown Co. have decided not to erect on the Big Betsey mine the stamp mill purchased last fall, as the free gold contents of the ore are said not to be such as to require it. Instead Cornish rolls, with a new boiler, are being installed. The ore, however, will not be chlorinated as assays do not show such values in the sulphurets as to justify such treatment. The crushed ore will be handled by a secret process for which the plant is now building. Laboratory tests of this process are reported to have shown a saving of the gold contents as determined by fire assay and the management is convinced that this method is peculiarly adapted to their ore. All the treasury stock is reported to be sold. The report that Rev. Mr. Jernagan of North Lubec, Me., has secured an option on the property seems to be premature.

Coulterville, Cal., March 22nd, '99.

Mono.

A strike in the Mono-Glen mine is reported to show ore of an assay value of over $30 per ton.

Nevada.

A mining deal is pending at Grass Valley. It is the sale of the Union Hill group of mines, recently acquired by E. Creller from the McLean estate, and which he proposed to reopen. He incorporated a company with 200,000 shares of capital stock and rapidly disposed of much of the stock. Further transactions in this line are in abeyance, owing to the desire of Capt. Thos. Mein to purchase the property.

At the North Bloomfield mine, North Bloomfield, an illustration of which appears on the first page of this issue, crosscuts are being made from the bedrock tunnel which is now in 600 feet and upraises are being made. When work was stopped the tunnel was in 600 feet. The contractors struck ground so hard that they quit. Then the company took it and put in two Ingersoll drills. After a few days they got into soft ground again and the drills were discarded. Meantime the bedrock had pitched downward into a "pothole." It is believed if the tunnel is extended the pothole will be crossed and the bedrock will be found pitching upward again, when the tunnel will be a success.

Tidings-Telegraph: The Phœnix mine is shipping ore.

Grass Valley *Union*: J. R. Ritchie is running the Huntington mill on his quartz claim at Omega.——The Tully Bros. have started drifting on their gravel mine at Omega.

Orange.

E. J. Kimball and J. M. Turner are prospecting the quicksilver deposits four and one-half miles east of Santa Ana. Two shafts are being sunk, the deeper one being down 60 feet. The ore occurs on a low hill and has been known for many years. Considerable superficial development has been done in past years, but no systematic effort made to develop the deposit. On the west side of the hill a long tunnel has been run in, but did not reach the ore zone. Specimens of the ore are high grade. It is chiefly meta-cumabarite.

There are copper prospects in the Trabucco canyon, several miles back of Santa Ana, some of which have superficial development.

Placer.

Pay gravel is being taken from the Wesley mine, near Iowa Hill.

The Boston News Bureau hears that the capital stock of the Pioneer M. Co. will be increased from 100,000 to 150,000 shares. The new stock will be sold for working capital, as the electrical equipment recently installed cost more than at first anticipated.

Plumas.

(Special Correspondence).—Taylorville and its vicinity are attracting attention on account of the work being done on their copper prospects. Parties are here prospecting and developing several groups of copper claims. The Ajax group, comprising three claims, has a vein said to be 60 to 70 feet wide. The Pittinger group has a vein 15 feet, of carbonate ore. The same parties are negotiating for the Reward, the Engels and the Sullivan groups. They have secured the Mountain Meadow group and the Starks boys' claims, all within a radius of ten miles of Taylorville. They have secured 6000 inches of water and right of way for ditch and railroad. A. B. Somers is representing the parties.

Taylorville, Cal., March 14th, '99.

Work has been resumed on the Whitney & Duncan mine near Genesee.

Plumas *Independent*: A. B. Somers has located the site for his smelter below Arlington and will begin building electric power works.——The Mineral Point mine, back of the Genesee mine, recently relocated by C. Adams, proves to have good ore. One hundred pounds sent to Selby went $210 per ton.——A. B. Somers has four crews at work on his new mines—Taylorville, North Arm and Genesee—and next week will send a crew to Mt. Meadows on the Fant & Gee property.

San Bernardino.

Fifty men are employed in the Rose mine, sixty miles east of Victor. The mine is situated at an altitude of 7200 feet, in the San Bernardino mountains, and has recently been equipped with a new plant. The vein occurs in limestone and mica schist following a granite dike. The ore is calcareous and contains considerable hematite, usually disseminated but sometimes massive segregations of high-grade copper ore occur, rich in gold. In its early history the ores of this mine gave considerable trouble in their treatment, but of late a high percentage is being saved. There are many other claims in this district, but the Rose is the the principal vein.

Rich gold and silver ores occur in limestone at Silver Reef, forty-five miles east of Victor, near Old Woman's Springs, but thus far the ore deposits have proven small and spotted.

San Diego.

T. J. Vandergrift of Pittsburg, who, with several other Eastern capitalists, holds the bond on the Bay Horse mine, near Glamis, in San Diego Co., is considering a proposition th pipe water from the Colorado river, eighteen miles, and will do so if the investigations he is now making prove its advisability. This mine is near the old Paymaster mine, to which water was pumped a distance of seventeen miles from the river.

Moreland Camp is six miles northeast of Glamis station on the S. P. Railroad. It has always been a favorite resort for dry placer miners. The ledges were covered by a mass of decomposed rock that capped the entire region. L. C. Moreland has sunk a shaft 200 feet and uncovered gold-bearing ledges.

In the early days of California many thousands of dollars in nuggets were picked up on the surface at a place called Pipendero, at the eastern base of the Cargo Muchacho mountains, but no ledges of consequence have been found as yet.

Shasta.

The development work on the Bryan & Sisk cinnabar discovery on Clover creek shows the ore to be continuous as the shaft is sunk.

Shasta *Courier*: It is reported that the Distlehorsts will put a dredge on Clear creek near Muletown.

Searchlight: A strike has been made in the Mammoth mine in a tunnel started a year ago and now in 900 feet, which cut a rich ledge. Thirty men are employed.

Shasta *Democrat*: J. Sallee has resumed shipping ore from Bully Hill at Copper City.——The main working shaft on the Mt. Shasta mine is now down about 300 feet. This company has nearly 100 men on the payroll.——The 5-stamp mill on the old Spanish mine at Lower Springs is running night and day.

Redding *Free Press*: A new mine is being developed near Copper City. W. Arps recently located four claims on a lode which he discovered. A drift was run on the lead and ore yielding $80 per ton in gold besides silver and copper was developed. The new discovery adjoins the Bully Hill mine. The owners of the four claims have located sixteen additional claims along the lode.——A rich strike in the Mammoth mine near Kennett is reported. The strike was made in the lowest tunnel. The tunnel was driven 900 feet before the ledge was finally cut and as far as they have gone through it is richer and larger than anything that has yet been found in that district. Twenty-five men are at work and the ore will be shipped to Keswick. There are 250 feet of backs.

Mountain Miner: The ledge which made the Uncle Sam mine has again been found and ore is being taken out. It is expected over 200 men will soon be employed at the Uncle Sam.

Siskiyou.

The Greenhorn Blue Gravel mine, one and one-half miles south of Yreka, has been yielding big returns in reopening the ground where the cave occurred over two weeks ago. There seems to be no doubt that the pay extends out into Shasta valley as well as up Greenhorn creek.——The Hazel M. Co. at Henley is still taking out paying quartz from the California Queen mine. There is talk of putting ten more stamps in the mill.——The American Bar Co. at Klamath river, in the Ash Creek section below Hornbrook, is now working day and night with a large force.

News: The Commodore mine, at the head of Barkhouse creek, has struck a rich body of ore. The tunnel on the lower level is in 476 feet and should strike the ledge soon.——Silvera Bros. are ground-sluicing their claim on Main Greenhorn. —— The Beaudery placer mine, on South Fork of Scott river, is about to start up.——H. Finley is running two arrastras on the Lanky Bob, in White's gulch.

News: At the North Fork hydraulic mine

on Greenhorn four men are employed on full time with one giant.——The tunnel at the Spencer mine is in about 800 feet.——Placer mines are all doing well. The water supply is abundant and the placer miners are taking advantage of the opportunity.

Yreka *Journal*: Several quartz claims have been located on the east fork of Callahans on the ridge between Shasta and Scott valleys, near the wagon road between Gazelle and Callahans. There are numerous ledges on the east fork above Callahans, and also in the Willow Creek section along the Gazelle side of this ridge.——The Cottonwood Creek company has steam boring apparatus and will sink to bedrock at different points along the creek bed and banks to test the gravel from the surface down. Operations are to commence in a few days.——The Commodore quartz mine on Barkhouse creek, Klamath river, is paying, four pounds of amalgam being taken from the plates of the mill on a twenty-four hours' run.

Trinity.

Five large hydraulic mining companies have united in an attempt to set aside the action of the County Board of Equalization in raising the Assessor's figures on their property valuations.

A placer claim on Indian creek, near Minersville, owned by Bergin & O'Neil is reported to have recently produced over $2500 in a sixty-hours' run, the water following the last rain creating the first opportunity in years to work the property.

Redding *Searchlight*: The improvements on the Bloss & McClary hydraulic mine, near Trinity Center, are about complete and a full force of men employed.

Tuolumne.

A rich strike is reported in the Pennsylvania-Carlotta at Cherokee, one mile from Summersville. The ore carries a heavy percentage of galena, pyrite and chalcopyrite, and is rich in gold, though little is visible. D. Nagle is Supt.

E. E. Bartlett was killed by a cave at the face of the north drift of the 900 level of the Rawhide mine last week.

The Scanovina mine, near Arrastraville, is said to be looking well. The ore is high-grade and the formation granite.

The Shawmut-Eagle mine, near Jacksonville, has a new safety cage for inclined shaft. A test was made a few days ago by loading the cage with 4000 pounds. The cage was allowed to drop but stopped in 3 inches. Without a load the cage stopped in 1½ inches.

An abundance of rain and snow in the higher mountains has fallen throughout the county. Several properties, idle owing to scarcity of water, will now be able to start at once.

Work has been resumed on the Bystander mine at Yankee Hill, near Columbia.

Contractors grading on the line of the Sierra railroad near Jamestown struck a vein of gold rock reported to be rich.——The ten stamps which have lately been added to the Black Oak mine are running.

At the Arrastraville mine, Arrastraville, J. L. Tonkins, Supt., after pumping out the water, retimbering and clearing out debris, a winze is being sunk in the lower level, 135 feet from the main incline, in which they have a vein 20 inches wide, heavy in galena and iron sulphurets. The quartz shows free gold.

The Black Oak M. Co. will supply the village of Soulsbyville with electric light. The line is about completed.

The Dead Horse mill is closed down because ore could not be extracted fast enough to supply it. Twenty men have been laid off. Drifting goes on.

The company organized to work the remnants of placer ground on Columbia, Independence and Shaw's Flat, having sunk a number of bore holes, now contemplate driving a tunnel under the ground from the canyon of the Stanislaus.

Independent: A 30-stamp mill on the Trio mine, near Jamestown, is contemplated.——The mill at the Dead Horse mine, near Carters, was closed down last week temporarily. Taking out ore is continued.——Geo. Mapes, who is operating a hydraulic mine at Yankee Hill, has found a nugget containing $500 in gold.——A 40-stamp mill at the Golden Rule mine at Stent is an improvement talked of by the owners.——An additional twenty stamps will be added to the mill of the Santa Ysabel mine at Stent, which will make a total of forty stamps. A new hoist at one of the shafts will also be erected.

Democrat: A 6-foot vein has been discovered in Mustang gulch, near Arrastraville, which assays $37 in gold and $9 in silver per ton.——Seventy-five men are on the payroll of the Golden Gate, with the probability that the number will be increased as a result of the rain.

Jamestown *Magnet*: E. T. Hale, Supt. Rawhide mine near Jamestown, will make some changes in the plant. A canvas plant to handle the slimes has been decided upon, and a rotary mill for regrinding the tailings is to be put in. This will increase the capacity of the mill 25%.

Yuba.

The Victor Gold Mines Co. is developing the old Pennsylvania mine, it is reported, with good results. A new ore shoot is receiving particular attention, being reached by a system of crosscuts on the 600, 700 and 800 levels of the old workings.

COLORADO.

BOULDER COUNTY.

The Delano mill, at Boulder, is about to start up again under new management.

W. Rose, operating in the Cashier tunnel at Salina, last week found a 3-inch streak of tellurium which will run about $8 a pound.

A strike was made in the No. 2 shaft of the Victoria recently by Lampshire & Co. The ore was discovered in the 300-foot level.

The Grand Republic, on Four-mile, has been purchased by Colorado Springs parties and started up. A shafthouse and dwelling house have been erected.

The Typhenie, worked by Herival & Billemin, is producing tellurium. The last shipment of high-grade stuff ran nineteen ounces.

Boulder *News*: A strike of gray copper was made by leasers in the Evans tunnel, near Salina, recently.——The Ingram is working fifteen men, using five machine drills. The production last month was sixty tons.——The Little Johnny, at Salina, owned by F. Vand, is being worked under lease and bond by D. G. Peabody of Denver.——Twenty-six men are at work on the Emancipation, at Salina.

Ward *Miner*: At the Silent Friend, at Sunnyside, work has been commenced on a station in the tunnel, 300 feet from the mouth, in which to install a steam hoist for further sinking the shaft started there.——A good strike was made in the west lower level of the Ruby mine recently, where 5 feet of ore was opened up, the larger portion being milling ore, although there is a wide streak of solid smelting ore.

CLEAR CREEK COUNTY.

Denver *Mining Record*: Mining for zinc ore is a new and profitable industry near Silver Plume. Mr. Colley, a Leadville miner, lately leased the Mendota mine, from which shipments of zinc ore to Upland, Indiana, have been made that carry 50% zinc.

Denver *Republican*: A large electric plant is to be put in near Dumont to furnish light and power to mines in this county. The first plant erected will have a capacity of 2000 H. P. This is being contracted for at $100 per H. P. per year, a saving of one-half the cost with steam. Water from Clear creek will be used in driving the machinery and the minimum power at Dumont will be 2500 H. P. When the reservoir at Empire is completed it will be much heavier. The company has rights below Idaho Springs which will add 3500 H. P. for an auxiliary plant.

CUSTER COUNTY.

The Bassick mine has been unwatered to the 500 level through the new shaft. The old workings have been found badly caved.

EL PASO COUNTY.

The value of the output of the mines of Cripple Creek and vicinity for February was $1,283,750, which was about a quarter of a million less than the output of January, due to a short month and snow blockades.

Victor *Record*: S. N. Simmons and associates have been granted a twelve months' extension of their lease on the Zenobia, at Cripple Creek. This week's shipment from the mine consists of twenty-two tons of $30 ore; a shipment of high-grade is being prepared.——The Lillie is producing thirty tons a day from the upper levels of the mine, while sinking is in progress. The shaft is to be sunk to the 600 level.——Lessee F. O. Wood is sinking with air drills on the new Mineral Rock shaft. The output is steadily increasing and last month reached 300 tons. An average of all shipments is better than $90 to the ton.——The $85,000 bond on the Silver Tip claim of the Enola Co., Cripple Creek district, held by Chicago capitalists, was taken up. It will be developed by either the company or lessees.

GUNNISON COUNTY.

(Special Correspondence).—Messrs. Webb & Knox have been working on a property called the Sadie D., about three miles east of Iris. They now have the shaft down 40 feet on a good vein 6 feet wide. The vein at the surface only ran from $2 to $3 in gold. Samples from the bottom of the shaft show an average value across the vein of $20 per ton in gold. Webb & Knox represent Eastern people, who will push the sinking as soon as spring opens.

O. H. Knight has just arrived from Leadville and expects to start up the Raymond mine, which has been idle for some time, but in times past has produced considerable good ore. Mr. Knight expects to soon put it in line for regular shipments.

The Grafiin property has been closed down for a few weeks till Mr. Grafiin returns from Chicago, where he has gone to attend a meeting of his company. His men working near Volcano are still at work and will push development as fast as possible.

Work has been commenced on the Gunnison mine on the 100-foot contract of sinking. A contract has also been let to same parties to run a crosscut to the vein when the sinking is done, which will be about 60 feet in length. The force is at present unwatering the mine. A boarding-house has been started for the accommodation of the men.

A strike is reported near Marble, in the northern part of the county, in what has always been considered a silver, lead and copper camp. But the returns from Leadville show $14,000 in gold from a flinty or schist-like quartz. Prospectors will pay more attention to gold values in the future on Crystal river.

Another strike in gold ore is reported from near the same place, but the figures are fabulous. When the present 10 feet of snow is gone we shall know more about it.

Gunnison, Colo., March 18th, '99.

(Special Correspondence).—It is said the purest copper produced in Colorado comes from the Lead King mine at Crystal.

The following mines have received returns from the smelters and reduction works on copper values: Lead King, North Pole, South Pole, Catalpa, Carbonate, Lulu, Daisy, Prospect and Agatha. In the four first named copper predominates, and in their shipments the silver, lead and other values have been the side product, the ore being mined for its copper value.

A promising property that has been opened up in this district is the Burt, where development work has been done since June of last year, and in which large bodies of ore are exposed in three tunnels, carrying a high percentage in copper, with good values in lead and silver and a small return in gold. By June 1st the company will have a tramway to convey the ore from the mine to a point on the roadway, where it can be loaded for shipment.

Copper shipped from this district has been principally chalcopyrite, a sulphide of iron and copper, and carbonate (malachite). In most instances development has shown the copper values to improve with depth.

Crystal, March 18th, '99.

HINSDALE COUNTY.

The strike at the Ute and Ulay mines at Lake City is over, and both mines are again in operation.

LAKE COUNTY.

G. W. Cook of Leadville has a contract with the Illinois Steel Works at Chicago by which it is expected that Leadville will ship 60,000 tons of manganese ore between now and Jan. 1, 1900. The contract calls for the delivery of 30,000 tons at the Illinois Steel Works. In addition, the Colorado Fuel & Iron Co. is being supplied with manganese from that point. The ore comes from the Catalpa-Crescent and Garden City properties. The output will average 200 tons a day. Many of the steel works in the East get their manganese from foreign countries, and Mr. Cook had a hard fight to get that contract for Leadville. Last year the output of manganese iron was 20,000 tons. This year the new contract will treble this, which means that these manganiferous properties will give employment to double the number of men they have in the past.

Leadville *Miner*: The President shaft, on the north end of Breece hill, is opening a fine body of silicious gold ore. Silicious ores are in demand at the smelters.

Leadville *Chronicle*: The smelters are returning to their normal condition. During the most severe weather the Arkansas Valley smelter was only able to keep four of its furnaces running, but has now seven in blast.——G. W. Cook has a force of men on the Garden City shaft in California gulch. A new plant is being put in. It is the intention to make it a large manganese producer. The Eastern steel works will take all of this ore which Leadville can furnish.——Mgr. Horner of the Catalpa-Crescent is preparing for a large increase in shipments,——At the A. Y. and Minnie, Leadville, the average shipment is 1500 tons per month. This property has developed into one of the great lead mines of the camp, about 350 tons of lead being supplied each month to the smelters.——The McAllister lease on the Mike and Starr will soon be shipping forty to fifty tons of copper sulphide, a considerable quantity of which will go to the smelter at Buena Vista.——The scarcity of timber continues and has interfered with mining operations. Several shafts have been temporarily stopped on account of the inability of the lumber dealers to furnish the necessary supply.——The Midland has from twenty-five to thirty cars on the side tracks along the Frying Pan and these will be rushed in the first thing.——Mgr. Schlessinger of the Weldon at Leadville is at present putting the new shaft, east of the big plant, in condition to be operated. A drift connects the two shafts, and the object is to reach the connecting drift, clean it out and secure air.——The Moyer has sent out this month 3000 tons. There are at present about 100 men on the Moyer payroll, and the tonnage can be raised to 300 tons per day just as soon as the conditions will permit of such an output.

Miner: The Fortune, Penfield and Judge Bowen group on Little Ellen hill, Leadville, are shipping gold ore to Pueblo.——The All Right shaft of the Crysolite mine on Fryer hill, Leadville, is producing manganese-iron ore.

LOS ANIMAS COUNTY.

A Boston syndicate, represented by C. H. Venner & Co., has secured control of the Copper King smelting plant at Trinidad, and purpose operating it independently of the recently formed smelting trust. A working capital of $300,000 will be provided.

MONTROSE COUNTY.

Denver *Mining Record*: Teams are hauling ore from the new copper mines in Paradox valley. J. N. McBride owns a controlling interest. Smelter returns have been received on the first eleven carloads. The ore will run about $1000 to the car of ten tons. In exact figures, $10,155.67 was received from 112.890 tons, or $89.96 to the ton as average.

SAN JUAN COUNTY.

Silverton *Standard*: The Gold King mill at Gladstone will again be enlarged. Twenty stamps, shaking tables, etc., will soon be put in, making fifty stamps. The extent of the ore bodies has never been demonstrated.——A foot of gray copper and lead was recently found in the shaft of the Pride of the West at Silverton, picked samples from which assays 400 ounces silver and 52% lead.

Silverton *Standard*: The rich ore discovered by McPhillips at Bear creek, in the Grape Vine, is in a fissure, between lime and slate.

SAN MIGUEL COUNTY.

San Miguel *Examiner*: The Liberty Bell mill at Telluride is dropping twenty stamps, treating sixty tons of ore every twenty-four hours. The additional twenty stamps being added to the mill will be dropping before a great while. The mine is in shape to supply the ore needed.——The Philadelphia mine at Saw Pit is in operation again and is sending out a good shipment at a profit from the smelter. The shipment from the camp is gradually increasing.——The Bessie mill at Telluride is now making two test runs of 100 tons each—one from the Montezuma vein and one from the Baldy. One-fifth of the ore is taken as samples as it leaves the rolls, and samples will be taken from the tailings which are to go to the Argall works at Florence for treatment by that process.

SUMMIT COUNTY.

Summit *Journal*: A strike of rich ore has been made in the Uncle Sam mine, at Swandyke, in a tunnel 205 feet from the mouth. The vein is 4 feet wide.

IDAHO.

The Trade Dollar Con. M. & M. Co. has absorbed the Trade Dollar and Florida Mountain companies, taking over all the mines, mills and other property at Dewey.

Buffalo Hump, the mining camp, is the Mecca of hundreds of people. There are about 100 in camp and more going in. There are absolutely no accommodations and only a little grub for those who are there. The snow is 12 feet deep, and it is impossible to do anything. Many locations are being made and sold at Grangeville at good prices; but when the snow is gone, purchasers will find the ground belongs to some one else.

A mining deal involving $200,000 in the Seven Devils is pending. The properties have been bonded to L. A. Hall and associates of Minneapolis and Duluth. The property consists of twelve claims lying east and west of the Peacock mine.

Spokane *Chronicle*: Jno. O'Neill of Central City, with several partners, has drained a small sheet of water known as Buffalo lake, near the Buffalo Hump mines, and located a number of quartz claims on the area formerly covered by water. The lake was nearly round and about 2000 feet in diameter. The water was 4 feet deep. It is claimed that the Buffalo Hump lead strikes directly into the lake.

Mullan *Mirror*: The capacity of the Morning mill at Mullan has been increased seventy-five tons per day by the addition of new machinery. In '98 the Morning mill produced in six months 16,280 tons of ore.

MICHIGAN.

The American Steel & Wire Co. has about completed the purchase of one of the Clarke & Sauntry iron mining properties in the Lake Superior region for $1,000,000.

MONTANA.

It is reported that the increased activity of the mines of Butte City will give employment to 2000 additional men.

The Parrot Co. will hereafter declare monthly dividends of 30 cents per share, or at the rate of 36% per year.

An explosion was caused last Friday at the smelter of the Montana Ore Purchasing Co., at Butte, by an icicle being thrown into a pot of boiling slag, just drawn from the furnace, Considerable damage to the machinery and men resulted and the building caught fire.

Philipsburg *Mail*: Both the Granite and Bi-Metallic mines are working and men are daily being added to the force; 100 stamps are now dropping. It is probable the Granite concentrator will be enlarged.——Several feet of copper ore is said to have been struck on the main fork of Boulder, five miles east of Princeton.

Clancy *Miner*: A strike was made in Lump gulch recently in the Sailor, owned by McKenzie, Nelson and others. The find was made in a short crosscut tunnel driven to strike the lode, and the face of which is not more than 15 feet under the surface. From 4 to 6 inches of high-grade ore is exposed in crossing the vein, resembling that from the Little Alma.——The leasers on the 150-foot level at the Legal Tender, near Clancy, are reported to be working in good ore.

NEVADA.

A 10-stamp mill is to be erected at the Golden Eagle mine in Humboldt county.

Comstock tunnel stock is reported in present demand in New York since the installation of the Risdon pump plant, shares appreciating from 4 to 10 cents.

Following is a copy of the weekly letter of Supt. G. McM. Ross to the Comstock Pumping Association, containing interesting matter relating to the additions to the Risdon hydraulic plant and demonstrating that lowering of the water 500 feet below the Sutro tunnel level in the C. & C. shaft will drain a large area of the Comstock lode: During the past week no pumping has been done. The work of the association being for and on account of the various mining companies as appear in their weekly letters. The Hale & Norcross Co. are repairing their connecting drift with the tunnel south lateral and their station on this level so that the action of the pump may be noted. The movement of the water in the Chollar combination shaft is such as to prove that a large area of the Comstock will be drained when the water in the C. & C. shaft has been lowered 500 feet, and for this reason it is important that the lowering of the water should be noted at as many points as possible. The Risdon Works, through their engineers now here, report that they are confident of being able to carry out their contract of providing machinery that will lower the water at the C. & C. shaft for 500 feet below the Sutro tunnel. They regard the present work as being experimental only in so far as they have to deal with greater pressure of water than has been used before in an elevator. The general principles governing the operation of such a system were well enough understood by them when they entered into their present contract. The machinery for the rearranged elevator has arrived and consists of a new tapered discharge made of phosphor-bronze and iron in sections, in all 23 feet long, as against 10 feet, the length of the first tapered piece used; a new suction piece, providing a much more liberal clearance, decreasing the velocity of the incoming or suction water to about one-tenth of what it was in the first suction used. Provision has also been made for moving the jet or nozzle a much greater distance from the throat, thereby securing a more thorough entraining of the incoming or suction water with the jet power water. They have also sent bolts and rods enough to permit of a submergence of 200 feet. All of the new work seems to be first-class in material and workmanship, and if there is no interruption we are likely to be pumping again within three or four days.

Under date of the 23rd it is learned that the machinery is expected to re-

sume unwatering to-morrow or Monday. All the old attachments have been taken out of the shaft, and the new elevator was yesterday lowered into place.

On the Comstock the Justice mine reports that on the 370-foot level they have drifted north from the top of No. 1 upraise. The face is in ore assaying gold $10.85, silver six ounces; total, $14.63 per ton. During the week they hoisted twenty-six tons of ore from No. 1 upraise, car samples averaging gold $20.69, silver five ounces; total, $23.71 per ton.

Silver State: Five or six miles south of Silver Peak are the Sand Hills, known to contain gold from 50 cents to $2 per ton; there are millions of tons of it.——It is reported that the 70-foot ledge at the Drinkwater mine, in Silver Peak district, averages $15 per ton in gold. Before striking the ledge the mine was offered for $500,000, but after they found this ledge they raised to $1,000,000.

Tracy & Mulhall of Salt Lake City have gone to Galena with a load of mining supplies to begin work on mines in Galena under the management of the Nevada M. Co., recently incorporated in Salt Lake.

White Pine *News*: The Chainman mine is making some interesting development. Recently a caved drift was cleared out and in a crosscut it was discovered that what had been taken for a footwall by former workers was only a clay seam a few inches in thickness back of which lay an 8-foot vein of good ore. The mine has lain idle for some time. It has a 75-stamp mill.

Enterprise: The Obiston shaft on the Comstock is to be reopened.——In the Con. Cal. & Va., the work of reopening the 1400 level is progressing. There is considerable unprospected ground on this level which will be explored. The 1650 and 1750 levels are also being placed in good condition.

Salt Lake *Tribune*: A few months ago Pease, Johnson & Bradbury took a group of claims, supposed to be low-grade, at Battle Mountain. They began work and had gone but a short distance when lead was noticed coming in. This was followed, and assays demonstrated that it had developed into a high-grade silver proposition. The ore is now being shipped at a profit.

NEW MEXICO.

An addition of thirty stamps is being made to the Aztec mill, near Elizabethtown.——The shaft of the Confidence is still in ore.

Santa Fe *New Mexican*: Forty men are leasing in the second and third levels of the Snake at Hillsboro.——A strike of high-grade ore is reported in the Mastodon at Hillsboro. The vein is 1 foot wide assaying $70 in gold and $20 in copper per ton.——The mines of Hillsboro are increasing their working forces and output. During the week the Opportunity mine put on ten new leasers; the Richmond has seventy-eight men employed, the Trippe eighty, Golden Era group fifty-five and the Woolsey thirty-five men.——Keller & Gallee have purchased the American mine for $11,000; J. A. Kruse of Chicago has purchased the Prosper for $10,000, and Postmaster Miller has sold the property he has been developing for $6000.——E. D. Baker made a shipment from his mine at Silver City which returned 15% to 30% copper.—— Noble & Miller of Paschal, have made a shipment of high-grade copper ore to the Deming sampler.——On Legal Tender hill, Silver City, C. Sellman has a prospect. The ore runs $6 in gold, seventeen ounces in silver and 4½% lead per ton.——The smelter at Silver City has closed a contract with a Crittenden, Ariz., concern for twenty tons of copper pyrite ore daily for one year.——At Chloride Flat, three miles from Silver City, fifteen miners are working old properties under lease. The ore is iron-lead and averages forty ounces in silver per ton.

Silver City *Enterprise*: Ashton, Roach & Williams have made a shipment of copper ore to the Silver City Reduction Works.——Ashton & Roach have resumed operations upon their Wildcat mine, which lies southwest of the Santa Rita C. & I. Co.'s mines.——A small force has been put to work upon the Little Fannie mine, at Mogollon.——H. Dawson still continues development work upon the Ivanhoe mine, near San Jose. He has about ten tons of copper sulphide ore upon the dump ready for shipment.

White Oak *Eagle*: Quartz leads have been discovered in the Jicarillas during February and March. Placer mining has heretofore had the entire attention of mining men in the Jicarillas, but now a number of parties are sinking on veins.

Silver City *Enterprise*: Jones & Dawson have sunk a new shaft to the level of the ore bodies on the Rita and are drifting east tocut the ore. The old shaft became unsafe and had to be abandoned.——H. Dawson has eight miners at work upon the Romero and is shipping high-grade ore.

OREGON.

(Special Correspondence). — Goodspeed & Fuller of Carson have bonded their placer property on Pine creek, Union Co., to Denver, Colo., men for $35,000, comprising eleven claims (220 acres) and water rights.

Baker City, Or., March 18th, '99.

The Collateral mine, adjoining the Virtue, near Baker City, Or., has 1800 feet of development work and has exposed a body of ore.

The Badger M. & M. Co. at Susanville is running the new 10-stamp mill on good ore and shipping carbonate ore from the Badger mine, also several carloads of high-grade concentrates from the mill.

Baker City *Epigram*: The development of the Denny group of mines near Baker City is to be commenced at once, with W. C. Nelson as Supt.——The Baisley-Elkhorn mine has made a cleanup of $6000.——The old Virtue mine, east of Baker City, is to be unwatered and water pipe is being shipped in.——Compson & O'Donnell have a bond and option on the Jay Gould mines near the Bonanza. J. F. Cupid of Sumpter is Supt.——A strike of copper ore worth $60 per ton is reported in the Vaughn mine on the Oregon side of Snake river. The vein is said to be 130 feet in width.

Idaho *Statesman*: The Cable Cove district is on the head of Silver creek, four miles west of Cracker creek, in Baker county, ten miles from the Sumpter Valley railroad. Timber is abundant, also water, except for power. The country rock is granite, traversed by numerous fissure veins, the longest of which has been traced and located for a distance of five miles. The strike of these veins is north, and shoots of ore come to the surface in many places. The ledges vary in width from 1 foot to 50 feet and carry very long ore shoots.

SOUTH DAKOTA.

The new Deadwood & Delaware smelter at Deadwood handles 400 tons of ore, 200 tons of limestone and a large quantity of coal and fluxes daily. The former plant burned about a year ago, but the new one is constructed of iron and steel. There are four blast and one reverberatory furnaces in operation and a second reverberatory has been completed.

The Montazuma mines, three miles north of Rockford, have been bonded to C. Cadmus.

The Portland, Clinton, Trojan, Empire and other mines on Green mountain are shipping again.

Pioneer-Times: The Dacy shaft, at Ragged Top, is down 455 feet and has passed from limestone into a calcareous sand rock. Pockets of ore are of frequent occurrence. The upper quartzite lies beneath the sand rock.

Black Hills *Mining Review*: The Ragged Top Co. has leased a portion of its ground to Pringle & Desmond, who are taking out ore.——The Kilpatrick shaft at Ragged Top is down 480 feet.——The Homestake Co. at Lead City contemplates making extensive improvements this year. A large amount of money will be expended in sewers and in securing additional water supply.—— Baggaley & Mauss are drifting from the bottom of the shaft in the Diamond mine on Two Bit. The vein is a fissure in rhyolite and consists chiefly of limonite ore carrying gold.——A single shift is at work on the Montana mine, near the head of Irish gulch, three miles from Rochford, driving the tunnel ahead.——The Standby, below Rochford, is in operation. The belt on which the Standby is located extends several miles south from Rapid creek, and on it are several good prospects.——Important work is about to be started in City Creek canyon, Deadwood, to determine the extent of the copper-bearing vein developed higher up on the mountain. It is said that, if the result of the contemplated exploration prove satisfactory, the Detroit & Deadwood Co. will build a large smelting plant near Deadwood for the treatment of the ore.

UTAH.

Lewisohn Bros. of Boston have bought the copper plant and its copper mines on Copper mountain, Box Elder county, for $200,000.

A Boston corporation known as the United States M. Co. has purchased the old Jordan mine, the Telegraph group, the Hamlin group and the control of the Niagara group of mines in Bingham canyon. As lead, gold and silver mines they are credited with a production of $25,000,000. Copper ore of high grade also occurs. The properties have recently been examined by Rich'd A. Parker of San Francisco, Wm. A. Farish of Denver, Wm. T. Austin of Denver and Jas. W. Neill of Salt Lake City, each of whom reported favorably. The mines are developed by twenty miles of workings and show large ore reserves. The company has also secured the site of the old Jordan smelter. The properties are already well equipped with mills, concentrator plants, cyanide works, etc., but a large reduction works will be built on the site of the old Jordan smelter. There is a canal eight miles in length which delivers a large supply of water at the smelter.

Bingham *Bulletin*: Ore is now coming from the Niagara, at Bingham, by tram at the rate of three cars per day.——At the Old Telegraph there are upwards of 500 tons of leasers' ore out.——Work on the Rough & Ready, now in new hands, is being started this week under contract by Morrissey & Hepburn.——The Yampa, opposite Highland Boy, is reported blockaded with ore.——Giant Chief hoist, idle for some time, is being repaired and will be busy this spring.

Salt Lake *Tribune*: It was reported that the properties and plant of the Sunshine M. Co. at Sunshine, Camp Floyd district, had been tied up by G. S. Peyton and others, and that a transfer of at least control would be made to them.

Mercur *Mercury*: T. B. Joseph has let a contract for running a tunnel on his Gold Flake ground in Ophir canyon. —— Considerable work is being done in the Cedar Hills group, West Dip, and the showing is good.——Work on the Kismet hoist has commenced.——A cave in the Geyser-Marion has disclosed a ledge of high-grade ore in a place where it was supposed no ore existed, as it was higher up than any ore body yet discovered in the property. —— Development work on the Wachusett group on Lion hill is progressing, the tunnel having been driven a distance of 130 feet. The vein, which was small at the start, has gradually widened to nearly 2 feet, showing values in silver and some gold.—— At the Mercur the regular four ore trains keep the mill grinding on 400 tons per day. The new refinery is almost completed, and the electric plant is expected to be in operation about April 15th.——The gold excitement on Antelope island in Great Salt Lake has reached Mercur and several miners and mill men have left for there.——At the Snowstorm, the 400-foot level has been reached and a drift started both ways on the vein, while sinking still continues on the incline.

Salt Lake *Tribune*: A strike is reported from the Century mine, in Park valley, Box Elder county. A vein 4 feet wide, containing a copper-gold ore, has been found in a new tunnel 125 feet from the surface.

Eureka *Republican*: The Illinois M. Co., at Eureka, has installed a new gasoline hoisting plant.——The Silver Bullion, at Diamond, is being developed with an increased force under the management of S. K. King.——The Superior M. Co., Tintic district, is putting down a shaft under contract and also erecting necessary buildings.

WASHINGTON.

Washington's new mining law may be briefly summarized as follows: Discoverer must file notice of location within ninety days from date of discovery; "before filing such notice for record the discoverer shall locate his claim by first sinking a discovery shaft upon the lode to the depth of 10 feet from the lowest part of the rim of such shaft at the surface," besides marking the surface boundaries as usual, and, if there is underbrush, blazing around claim; an open cut or tunnel 10 feet in length shall hold a as shaft; in case of previous filing being defective relocation must be made, as above; within thirty days after expiration of time for assessment work sworn statement must be filed with county recorder, giving nature of labor performed and cost, which shall be prima facie evidence of the facts; "the provisions herein relating to discovery shafts shall not apply to any mining location west of the summit of the Cascade mountains;" any mining district shall have the power to make road building to mining claims within such district applicable as assessment work or improvement upon such claims.

The Republic mine at Republic has been sold to Montreal, Canada, capitalists. The company will be reorganized.

The new company which purchased the Republic mine will be known as the Republic Con. G. M. Co. The incorporators are P. Clark, C. S. Eltinge and W. J. C. Wakefield. The capitalization is to be $3,500,000, in shares of a par value of $1 each. The office will be in Spokane.

In a new shaft on the Mary Ann mine, at Republic, at a depth of 12 feet they came upon a cone of solid copper-gold ore similar to the Rossland ores. It is a solid body of ore stretching across the shaft and extends for some distance on either side with no wall in sight. Assays show $3.80 to $14.60 in gold. The working force will be doubled and a tunnel started to tap the vein at a depth of 240 feet.

The Mountain Lion, at Republic, has put in a compressor plant, comprising an 80 H. P. boiler, a 42-inch by 10-foot compressor capable of running twelve drills. The equipment includes three Little Giant drills, Nos. 1, 2 and 3. The first work will be to continue the tunnel to cross the ledge which lies farther east. Drifting on the vein already opened will also be done. The Mountain Lion will soon be ready for a mill. It is the intention of the management to erect one this season.

The vertical shaft on the Dora at Republic is now down 45 feet. At 20 feet the shaft passed through the pay streak at an angle of 60°. Where it was first struck it was composed of stringers of quartz, but before it had all passed out it had become a solid ore body. The pay streak was about 4 feet wide where it was cut by the shaft.

The shaft on the Delta is down 25 feet in solid quartz. A crosscut has been made at the bottom, showing the ledge 10 feet wide. The average value of the ore in the Delta will run $10.

The vein on the Kate Hayward has straightened up and the shaft is now being run straight down. A tunnel is being run on the Kate Hayward to tap the shaft.

The Flag Hill has some rich ore. The vein ranges from 10 inches to a foot in width.

A shaft is being sunk by the El Caliph upon the line between that property and the Morning Glory which is down about 25 feet. The crosscut tunnel is now in 100 feet.

Rossland *Miner*: The report of a strike comes from near the mouth of Gold creek about sixteen miles south of Republic. It is gold and assays are reported high. As yet the snow is quite deep and details are meager.——The Snow Drop shaft is down 50 feet, and has 4 feet of quartz, which assays $14.40. Drifts will be started from the 75-foot level.—— Supt. Donan of the Nevada claim has struck a seam of 8 inches of ore. The tunnel will cut the ledge at a depth of 250 feet. The surface ledge is wide and assays fairly good

WYOMING.

Salt Lake *Tribune*: The record of a forty hours' run at the Carissa mill is $3600 worth of gold bullion. The average output of the mill is about fifty ounces of gold per day.——T. H. Neff is hauling ore from the Mormon Crevice, and is preparing to start his mill in Atlantic gulch.

Grand Encampment *Herald*: The Meta mine, near Grand Encampment, has a vein of 18 inches of shipping ore. The workings are down 75 feet and a body of high-grade ore is at the bottom of the shaft. The water level was reached at 65 feet, and the company will put in pumps, hoists, etc. There is on the dump three carloads of high-grade silver, copper and lead ores ready for shipment. This property is owned by the Carbon County Copper Co.

FOREIGN.

AUSTRALIA.

The Western Australian International Mining and Industrial Exposition was opened at Coolgardie last Tuesday and will continue for three months.

The output of the Western Australia gold fields for December, '98, was 95,316½ ounces. The production of that section has steadily risen from 302 ounces in '86 to 1,050,180 ounces in '98. The total output for thirteen years was 2,692,793 ounces, valued at $50,000,000. In '98 New South Wales produced 341,722 ounces, Queensland 918,000 ounces and Victoria 837,258 ounces.

BRITISH COLUMBIA.

Work on the Fontenoy mine at Camp McKinney has been commenced under direction of P. L. Egan. The Fontenoy carries two ledges, which cross each other at right angles. One of these is a base ore vein and the other is the Cariboo ledge, which runs through the Wiarton and Waterloo into the Fontenoy.

The lower tunnel on the ledge of the Hamilton group on Twelve-mile, near Silverton, is in over 100 feet. This property, opened by the owners, has over 200 feet of tunnel driven.

The Emily Edith mine, on Slocan lake, will probably build a 200-ton concentrator the coming season. The Wakefield Co., Slocan, are considering the building of an aerial tramway.

The Snowshoe mine at Greenwood is reported bonded to J. W. Astley for $70,000. The mine is developed by an incline shaft 170 feet, several crosscuts and drifts. The ore is copper pyrites in calc spar.

The Canadian Pacific Exploration Co., owning the Porto Rico mine, near Ymir, has shut down the mill on that property owing to lack of water.

On the Treasure Vault, just below the Last Chance mine, in the Slocan, a strike of 2½ feet of clean galena has been made, and on the Vulture, beyond the Reco, a drift has been run 20 feet on 18 inches of clean galena and 2 feet of concentrating ore.

Rossland *Miner*: The Oro Fino Mines, Ltd., located near Fairview, is to have a mill. The No. 2 tunnel on the Oro Fino ledge, which was on Feb. 9th in a distance of 86 feet, and proved the ledge to be 4 feet wide at that point, assaying $47.50 per ton, has now (the 16th inst.), at 118 feet, shown the ledge to be 8 feet wide. The ore is high grade and free milling.

Spokesman-Review: At the Golden Wedge property, near Nelson, a strike has been made in the lower tunnel, which is being driven at a depth of 400 feet below the upper workings, where a ledge of quartz carrying galena and free gold was found. The new 10-stamp mill on the property is now complete, the equipment including three vanners.

Ymir *Miner*: A strike has been made on the Monarch group, near Ymir. The ledge on this property is 50 feet wide, and the shaft sunk in the center of the ledge has struck the footwall at a depth of 60 feet, where a chute of ore showing a high percentage in copper has been fcund.——A large force is working in the Dundee mine, near Ymir, and the concentrator is now running. A contract has been let for 100 feet of drift from the 200 level.——The contract for sinking a shaft 100 feet on the Evening Star has been completed. It is owned by the Fairmont G. M. Co. and is an extension of the Dundee.

SOUTH AFRICA.

RAND DISTRICT.

At the Crown Deep, in the Rand district, in February: Number of stamps working, 200; number of days working 200 stamps, 24 days 12 hours; tons crushed by 200 stamps, 25,541; yield in fine gold from mill, 6777 ounces; tons of sands and concentrates treated by cyanide works, 20,406; yield in fine gold from sands and concentrates, 5116 ounces; tons of slimes treated, 4300; yield in fine gold from slimes, 460 ounces; total yield in bullion ounces, 14,175, equal to 12,353 ounces fine gold; estimated profit, £23,550.

South African *Mining Journal*: In the first quarter of '98 the Simmer & Jack yielded £23,329; the second quarter, £52,174; the third quarter, £73,833, and the fourth quarter, £87,818. The estate revenue provided an additional sum of £12,934, and the total net profit on the year's operations was £246,531. This steady advance in yield and profits is to some extent accounted for by the appreciable advance in grade. In the first quarter the yield per ton was 7.688 dwts.; for the second, 8.928 dwts.; for the third, 9.613 dwts., and for the fourth, 10.01 dwts. per ton. Working expenses over the year average 19s 8.87d per ton, with a profit of 14s 4.62 per ton treated. During the last quarter the ore reserves were depreciated by 28,330 tons.

Standard and Diggers' News: In the Randfontein Estates Co. two new reefs have been discovered. In continuing the crosscuts from the second reef lately discovered on the Randfontein Estates property, the South Randfontein struck a third reef assaying 37 dwts. per ton. In a borehole put down on another portion of the Randfontein Estates property a fourth reef has been struck 6 feet wide assaying 12 dwts fine gold over the whole width. The footwall of this reef assays nearly 3 ozs. to the ton.

MEXICO.

The Esperanza mine at El Oro is reported bonded to an English syndicate, which puts up $100,000. The price of the mine is locally stated to be $3,000,000 gold; the option expires April 25th.

An unauthenticated statment comes from Mexico that the Candelaria mine, in the district of San Dimas, State of Durango, had been sold for a million dollars in Mexican silver. The property is owned by D. M. Burns and others of San Francisco, Cal., and was discovered over 100 years ago and has been worked, with the exception of short intervals, ever since. During its early history it was worked in a desultory manner, until in 1783 it came into the hands of Don Juan Zanbrano, who developed it extensively and worked it until the time of his death in 1807. and it is said that during this time he paid in royalty to the Spanish Government $11,000,000. As the duty was presumed to represent one-fifth of the gross output, it is probable that Don Juan took out $55,000,000 in silver from the mine.

But little is known of the mine from the date of the death of the Don until 1863, though it was worked by heirs of Don Juan in a small way. The workings caved and for some time it lay idle altogether. In the fall of 1863 the property was purchased by Americans, who made repeated but unsuccessful efforts to unwater the mine. In 1883 D. M. Burns and associates bought the mine and modern methods being applied the mine was soon cleared of water, and it soon commenced to pay handsomely.

The ore is milled to about 85% of its assay

value, which is said to be over $70 per ton. The gold constitutes about one-third of the value. The property has been extensively and systematically developed, and in recent years has been worked through adit levels, the lowest of which reaches a depth of 3500 feet under the mountain in which the vein occurs. No pumping is necessary and all power for operating machinery is supplied by a stream in the neighboring canyon.

El Paso Times: The new proprietors of the Dos Cabezas mine, in the Sierra Madre mountains, have started the Huntington mill at the mine, which is turning out a quantity of high-grade concentrates, and as soon as they can increase their motive power the 5-stamp mill will be started.

Two Republics: The titles to the following mines have been declared forfeited, under the law of June 2nd, '92, for failure to comply with the requirements of the law:

Two Republics: In the Hacienda de Jicorica, Joaquin Martes has discovered a mine of gold and silver. This mine is said to have been known for many years, but has been hidden till now.

Two Republics: S. H. Parson, from the Sierra Madre country, reports the discovery of a rich placer mine on a tributary to the Aros river. The Aros flows into the Yaqui river, and the placer diggings are in the State of Sonora, about sixty miles southwest of Nacori and 180 miles in the same direction from Casas Grandes. The placers are in the bed of an old river and two miles from the stream, to which the dirt was packed by the discoverers on burros, who claim to have washed out $6.50 from 100 pounds of dirt.

THE KLONDIKE.

A letter from Dawson says: This winter's work has far enough advanced with many holes to bedrock on all the creeks to show that there will not be any new strikes with the exception of Sulphur, and that will be very small, as it is very spotted and a light pay streak. There is no question but that more gold will be shipped out this year, but not one ounce will come from new creeks, excepting Sulphur. Last year the output, according to official reports, was $3,500,000 and this year may possibly reach $6,000,000. The richest claims will be about worked out, for they have a full force of men working this winter. Last year they were at a disadvantage as they could only work a limited number of men, owing to the scarcity of provisions. There are some very rich claims in El Dorado and Bonanza, but at the same time the richness did not justify the immense rush in here last spring. People imagined that this whole country was covered with gold, from the way they staked every creek, gulch, bench and hill, and even on the Dome, the highest mountain range here, dividing the Klondike and Indian rivers.

Up the river is the Stewart River district, where a good many are now prospecting. A great rush of stampeders went up to stake Thistle creek and is many tributaries; but it has proved to be a fake. White river is another tributary to the Yukon which has been stampeded and staked the entire length. Down the river, two miles from Dawson, is Moose Hide, which was stampeded in 1897 and re-stampeded again last year, although they have yet the first pan of pay dirt to show. Further down are Twelve Mile, Kentucky and Colorado creeks, all fake stampedes. There are a lot of men here who are always on the alert, and will chase off during the night to stake on the slightest rumor; then there is another lot here who want as many claims as possible, so they can unload in the spring to the "cheekakos," for they expect another big rush of gold seekers in the spring. The gold which is in this country does not justify any rush, for right here in Dawson there are 15,000 more than the camp can support; in fact any man coming to this country should have enough money and grub to last him at least three years, for a man cannot depend upon working for wages, for work is scarce and the seasons are short, in fact a working man is better off in the States. It looks well in print to read about $1.50 an hour in this country, but this winter wages are as low as $5 per day. On the rich claims they pay $1 per hour, but during these short days a man does not work over six to eight hours a day; then again one must take in consideration that he must sled his grub and outfit, which is all the way from 1000 pounds up, to where he is working, which may be from twenty-five to sixty miles, depending on where he happens to get a job; if he does not want to "mush" himself he can have it freighted for 15 cents a pound, or it may cost him as high as 40 cents a pound in winter, depending on the distance; in summer it runs up to 65 cents a pound. You can figure on about three to four months' work, but a man will not average ten hours a day.

A laboring man is better off outside than here, for living is very expensive. Luxuries, such as fresh potatoes, are $1 a pound; fresh onions, frozen solid, 50 cents a pound; turkeys, $1.50 a pound; oysters, $5 a can; sugar, 50 cents a pound; coffee, $1 a pound; condensed milk, 75 cents a can; fresh meat, 50 cents a pound; butter, $1 a pound. All kinds of canned goods are plentiful. Meals at restaurants have come down to $1.50 and $1. Drinks and cigars are 50 cents; a few 25-cent houses have opened lately, but you can taste the Yukon water in the whisky and the cabbage flavor in the cigars. Smoking tobacco is $2 a pound, chewing $3 a pound; all other goods at proportionate prices. There are several articles which are very cheap, but they do not come under the head of luxuries but of burden, namely, a hand sled and a pack strap. I have come to the conclusion that they were never intended for men, so I have wisely resolved not to make a beast of myself again, for life is too short. I have seen big, husky Swedes pack 100 pounds from here to Dominion, forty miles, not a mile of which is dry trail in summer, it being over moss, nigger heads and swamp, so you can imagine the load it is. Many a hardy man broke down in health last summer; they packed their heavy burden to the hospital and died. The hospitals are always crowded and at the present time most of the patients have the scurvy, but several have frozen feet. In many of these latter cases amputation was necessary. These patients are stampeders, for they rush off on these fake discoveries in the coldest weather, and we have mighty cold spells here.

Dawson City has the reputation of being a very lively camp and it was for a short time last spring after the gold cleanup of the creeks, but to-day it is very slow. Saloons, gambling joints and dance halls are almost deserted, which is not strange, as nine out of every ten men are broke and no work in sight, as the mines employ only a small number each, at most twenty men, and there are not more than twenty-five mines employing that number. It is sad to see the misery that is here: nine out of every ten want to go back to civilization, but have no means, many being destitute. The leading American citizens held a meeting some time ago and sent out a man with a petition to Congress for the relief of Americans. Dawson is very orderly for a mining camp. I admire the mounted police system; they are a gentlemanly body of men who enforce the letter. All the "bad" men with records, and many are here, keep very quiet and few gun-plays are made. There have been three suicides, two women and one man. Dawson has had her biggest boom and is rapidly on the decline; a year from now it will be a very small $5-a-day camp. Companies will work out the remaining gold in the creeks, and even now some are applying for bedrock concessions. Dawson has seen her best days and will never rise again, as mining is the only resource and placer mines are quickly worked out. If we had quartz mines the camp would become permanent, but with all the prospecting done here nothing has been found. There are men here who will still boom it—they are either in business or have a good many wildcat claims which they want to unload. I would not advise anyone to come here, for it is a country of hardship.

Industrial Notes.

—Congressional appropriations for Pacific coast improvements at the last session aggregate $3,806,963.

—It is conservatively calculated that the recent California rains are worth $20,000,000 to that State's industries.

—A telegraph line from Lake Bennett to Dawson, N. W. T., is being built. It will extend to Skaguay, B. C., by cable.

—A Rothschild bank in San Francisco, with $5,000,000 capital, is the latest financial report, but, probably, an unlikely one.

—The Pacific Iron & Nail Co. have conveyed to the Balfour-Guthrie Investment Co. the old Pacific Iron & Nail Works' property.

—E. C. Kelsey, city engineer, Salt Lake City, Utah, proposes to spend $25,000 in betterment of that city's water system.

—The San Francisco Savings Union is about to build a reservoir and a canal 10 feet wide, 4 feet deep, 27 miles long, at Elsinore, Cal.

—A phenomenal oil flow of 1000 barrels per day is reported from Coalinga, Cal., and considerable adjacent property is being bought.

—The Pacific and International Exposition at San Francisco was given a $250,000 appropriation by the California Legislature before adjournment.

—The surveyors who have been looking for a route to build a railroad from Jerome, Arizona, to some point on the Santa Fe Pacific, have been "called in" by W. A. Clark.

—The Consolidated Kansas City Smelting & Refining Co. has the '99 contract for furnishing the Western Union Telegraph Co. with blue vitriol.

—At Nanaimo, B. C., Dunsmuir's Alexandria coal mines are again working with a limited number of pushers, who have resumed work at the old wage of $2 a day.

—An American electric company will install a plant on the Atoyac river, twelve miles from Puebla, Mexico, to utilize water power from the canal constructed by S. de Mier at a cost of half a million dollars, and will transmit current to Puebla. The machinery will be of 2000 H. P.

—A contract for a 500-barrel flour mill in Shanghai, China—the first contract ever given a United States firm for a flour mill in China—has been received by the Edward P. Allis Co., Milwaukee. The milling machinery, engine, etc., complete will be shipped next month.

—The Pittsburg Iron Co. is to establish a branch at Seattle, Wash., for the manufacture of iron and steel for the Orient. Seattle reports that "extensive iron mines in Lower California have contracted to furnish the raw material, and last week the company asked for a rate on 10,000 tons of iron monthly, to be shipped to Seattle."

—Boise, Idaho, reports that the contract has been let for the construction of the railroad from Weiser, Idaho, to the Seven Devils, and by May two will be racing to the great copper camp, work having already been commenced on what is known as the Huntington route, by Orman & Crook, the Colorado contractors. A hundred miles of the Weiser road has been contracted for at the average price of $11,000 a mile. In advance of the completion of either road, ore is being shipped from the Seven Devils on barges. The ore is floated to Lewiston, nearly 100 miles from the camp, there placed on cars and shipped to the smelter.

Personal.

W. H. HAMILTON of Kingman, Arizona, is in San Francisco.

W. H. HAMILTON of Kingman, Arizona, has gone to Vancouver, B. C.

A. A. BLOW of South African mines is on his way to London, England.

LOUIS H. R. VON RUECEAU of Cripple Creek, Colo., has gone to Europe.

COLIN TIMMONS, a mining man of Chloride, Arizona, is in Denver, Colo.

WILL J. SCOUTT, manager Suffolk mine at Ophir, Colo., is visiting in Denver.

L. BAUER of Berlin, Germany, has been inspecting mines in the vicinity of Nevada City, Cal.

J. J. VALENTINE of the Wells-Fargo Express Co. in San Francisco, Cal., is making a tour of Mexico.

WM. PLUMMER has resigned his engagement with the DeLamar, Idaho, M. Co. and returns to England.

W. B. STEWART is master mechanic for the Con. Gregory-Bobtail Mines Co. at Blackhawk, Colo.

DAVID SWICKHEIMER of the Japan mine, Telluride, Colo., is spending a few weeks in San Francisco.

J. F. NEWSOME has been appointed assistant professor mining and metallurgy at Stanford, Cal., University.

GEO. W. HALL, Mgr. Eagle Bird mine, at Maybert, Cal., has gone to Wilkesbarre, Pa., on official business.

P. A. H. FRANKLIN, who has been examining copper properties near Milford, Utah, has returned to the East.

E. T. HALE, formerly Supt. Keystone mine, Amador City, Cal., is now Supt. Rawhide mine, Tuolumne Co., Cal.

GEO. DOWNEY has resigned the superintendency of the Omo mine, El Dorado Co., Cal. He is succeeded by P. P. Weber.

M. C. WILKINSON, a young Los Angeles, Cal., electrical engineer, has been appointed second lieutenant in the U. S. army.

CAPT. THOS. MEIN proposes a trip to Alaska as soon as the Union Hill, Nevada Co., Cal., purchase is settled, and, subsequently, to England.

F. E. YOUNGS, Mgr. California Mines Development Co. of Barkerville, Cariboo district, B. C., is in San Francisco looking for mining machinery.

H. H. WHIPPLE is now Mgr. Columbus mine at La Plata, Colo., former Supt. Thompson having left that property to take charge of the Chihuahua M. Co.'s work at Chihuahua, Mexico.

IRWIN MAHON of Denver, Colo., is promoting a project the purpose of which is to establish a tourist scenic route on the Colorado river from the Gulf of California to a point in eastern Utah. He thinks he has a plan of light craft that will shoot rapids under perfect control by means of electricity and water power appliances.

Commercial Paragraphs.

THE Stillwell-Bierce & Smith-Vaile Co. of Dayton, Ohio, are represented in Denver, Colo., by O. G. Smith.

THE Enterprise Machine Shop, at Denver, are manufacturing twelve 6x8 steam hoisting engines, under contract.

THE American Steel and Wire Co. announces that its business center hereafter will be in New York and its executive business will be transferred to Chicago and San Francisco.

THE Link-Belt Machinery Co. of Chicago have increased their capital from $250,000 to $375,000, and have planned a new wrought-iron foundry building 200 feet square, to be built of steel.

FAIRBANKS, MORSE & Co. recently sold from their Denver branch pumping and hoisting equipment for the Albion M. Co.'s property at Big Cottonwood, Utah; also a gasoline hoisting engine to the Bingham Copper & Gold M. Co., at Bingham, Utah.

THE Simonds Saw Co. has recently placed in the Crocket beet sugar factory several Marsh steam pumps. All of the pumps used in this factory are of this make and giving entire satisfaction. This firm has also just sold to the Alameda Sugar Co. a Marsh air compressor, used in connection with an air lift, to raise water from artesian wells. They have also shipped a Marsh sinking pump to a mine near Angels Camp, which is doing good work. These sinking pumps are extensively used in Colorado and other mining centers, over 150 having been placed within two years.

THE Union Iron Works of San Francisco has the contract for two large freight steamers for the American-Hawaiian Steam Navigation Co., with headquarters at New York. The company is to ply its craft between New York, Philadelphia, San Francisco and Honolulu, with the possibility of extending the route. The first steamer is to be turned out in April, 1900, and the second one at a later date. Each will have a carrying capacity of 8500 tons. The first vessel will be 410 feet long, with 51 feet beam, and a depth of 32 feet. Her engines are to develop 2500 H. P.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey, Strong & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING MARCH 14, 1899.

621,216.—MINING CAISSON—J. Buchtel, Portland, Ogn.
620,889.—JAR CLOSURE—C. K. Cooper, Carus, Ogn.
621,041.—ARTIFICIAL FUEL—J. T. Davis, S. F.
621,045.—CANNING TABLE—F. A. Dixon, San Jose, Cal.
621,301.—NUT AND WASHER—W. C. D. Evans, Norwalk, Cal.
621,236.—BOOT BLACKING MACHINE—F. H. Farmer, Los Angeles, Cal.
620,913.—FRUIT GATHERER—H. T. Griffith, Portland, Ogn.
621,246.—GATE—C. H. Huslam, Stockton, Cal.
621,087.—FARE REGISTER—S. C. Houghton, S. F.
621,088.—SMELTING FURNACE—House & Dupea, Tacoma, Wash.
621,091.—FLOORS, SIDEWALKS, ETC.—P. H. Jackson, S. F.
621,305.—REAMER—J. B. Kaiser, Salem, Ogn.
621,264.—FRUIT CUTTER—W. Madison, Los Gatos, Cal.
621,130.—DISPLAY STAND—R. L. Peyton, Oakland, Cal.
621,281.—FRUIT GRADER—R. Powell, Myrtle Creek, Ogn.
621,149.—NON-OVERFLOW FOR VESSELS—C. L. Schalitz, S. F.
621,153.—TRUING WHEELS.—J. G. Schmidt, Portland, Ogn.
621,174.—WINDOW SASH WORKER—C. H. Strauss, Port Gamble, Wash.
621,175.—CURTAIN RING—Jennie L. Sturtevant, Gilroy, Cal.
621,062.—WATCH—F. W. Waschan, Medford, Ogn.

NOTE.—Plain and Certified Copies of U. S. and Foreign patents obtained by Dewey, Strong & Co., by mail or telegraphic order. American and Foreign patents secured, and general patent business transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

NON-OVERFLOW FILLING ATTACHMENT FOR CLOSED VESSELS.—Carl L. Schalitz, San Francisco, Cal. No. 621,149. Dated March 14, 1899. This invention relates to a device which is especially designed for the filling of casks, tanks and similar closed vessels and a means whereby the supply of liquid is automatically cut off when the receptacle is full, thus preventing any overflow of the liquid and notifying the operator when the filling is completed. Such devices are especially needed in connection with the transfer of wines and liquors from one tank or cask to another, either by gravity or by pumping. It consists essentially of a curved liquid inlet passage, a supplemental air passage following the curvature of the inlet passage and the vertical tube into which the air passage discharges, said tube having the lower portion chambered or enlarged, a piston upon the stem which extends downwardly through the horizontal portion of the filling passage, said piston remaining normally in the enlarged portion of the tube so that the air can freely escape around it. A valve chamber is situated in line below the air escape pipe with a valve fixed to the lower end within the chamber, which closes upwardly against a seat between the chamber and the filling passage so that the liquid rising into the air passage after the receptacle is full will lift the piston until it closes the inlet end of the tube and the valve closes the filling passage.

DISPLAY STAND.—R. L. Peyton, Oakland, Cal. No. 621,130. Dated March 14, 1899. The object of this invention is to provide a plurality of movable interchangeable stands upon which a display of goods may be made in store windows or at other points and a great variety of positions and forms for the display obtained. It consists essentially of vertically adjustable standard with disk slidable thereon having holding screw and peripheral upturned flange with grooves in the upper edge. Holes are made through the disk in line with the grooves and arms having the inner ends bent to fit in the holes are adapted to rest in the grooves, where they extend horizontally and radially outward to form supports around

the disk. Bracket pieces are similarly fitted to the vertically adjustable standard and boards may be attached also as to be tilted in various directions to support the goods in any desired position or manner.

WASHING AND CANNING TABLE.—Frank A. Dixon, San Jose, Cal. No. 621,045. Dated March 14, 1899. In the canning of fruit it is desirable to first wash the fruit before placing it in the cans and immediately remove it to prevent soaking and discoloration. It is difficult for the operator to remove and drain it and place it in the cans, necessitating constant dipping of the hands in the water, which is apt to make the operators ill. In my invention I employ an extended framework divided into separate working spaces having a continuous tank within and beneath the framework with a horizontal shelf and vertical wall rising therefrom; a shallow tray is fitted to each compartment having a screen bottom and the upper edge of the tray is hinged in line with the shelf so that when the tray is raised its front wall is substantially continuous with the shelf, and by placing a stop to support the rear end of the tray the water will drain out rapidly and the fruit will be in a position to be easily drawn forward onto the shelf and placed in the cans or other receptacles.

FLOOR, SIDEWALK-VAULT ROOF, OR LIKE STRUCTURE.—Peter H. Jackson, San Francisco, Cal. No. 621,091. Dated March 14, 1899. This invention relates to improvements in construction of artificial stone or concrete floors, roofs, combined sidewalks and roofs of vaults, bridges and the like. It consists essentially of parallel I beams with intermediate ribs formed of a body of concrete and bent strips of metal upon which the lower part of the concrete ribs rest, while the ends abut against the webs of the beams. These strips have means for securing them in place and for regulating the tension consisting of plates or clamps with which the ends of the strips are interlocked, said plates having their lower edges supported upon the lower flanges of the beams and belts extend through the clamps and the webs or ends so that the clamps may be drawn toward the webs and the tension upon the die strips increased. Roughened bars, rods or rails are embedded in the concrete body which forms the connecting rib and a floor rests upon this concrete body consisting of a corrugated metal bottom having a superposed thickness of concrete or artificial stone.

POSITION WANTED by experienced cyanide man in charge of a mill. Technical graduate. Good chemist and assayer. Speaks Spanish. Salary moderate. Address K. C. N., Mining and Scientific Press.

WANTED--AN ASSAY BALANCE
IN GOOD CONDITION.
State price and make. Address H. A. C., this office.

MINING ENGINEER WANTS POSITION. Thorough chemist and assayer; practical experience of stamp milling, chlorination and cyanide processes. Three years' experience examining and reporting on mines. Familiar with Mother Lode. Any capacity; moderate salary. Address "B. L.," this office.

A MINING DETECTIVE.—"Confidential," operating in California, Arizona and Colorado. I am prepared to investigate as to habits of employes on duty (also off duty) in mine and mill, particularly the art of stealing gold specimens, amalgam, ores, etc., from mining companies. Best of references. Reasonable terms. Address "Confidential," M. & S. P. Office, San Francisco, Cal.

WANTED—Position by a Mining Engineer Assayer and U. S. Mineral Surveyor.
Speaks Spanish fluently. Best of references. Address P. C., this office.

WANTED—SITUATION BY A PRACTICAL MILLMAN AND ASSAYER.
Would go anywhere Best of reference. Address F. B., care of Mining and Scientific Press.

WANTED — POSITION BY A CHEMIST, ASSAYER and MINING ENGINEER.
Cyanide a specialty. Speaks Spanish. First-class references. Address Box 28, this office.

WANTED---A PRACTICAL ASSAYER.
GOLD HILL QUARTZ MINING CO.,
Gold Hill,.....Oregon.

WANTED.
Capital to Handle Extensive Gold Mines.
JAMES ARTHUR, Cornucopia, Oregon.

Wanted to Bond a Gold Mine
IN CALIFORNIA OR ARIZONA, on which parties will do development work.
Address P , 347 Wilcox Building, Los Angeles, Cal.

Have Purchasers for Good Copper and Gold Mines
IN THIS STATE, ARIZONA AND MEXICO. Reliable reports required and options later, if approved of. RUSSELL & POOLEY,
349 Wilcox Building, Los Angeles, Cal.

..CRIPPLE : CREEK..
FOR SALE—CYANIDE PLANT,
100 tons daily capacity; in first-class condition to handle Cripple Creek ores.
Plant in full running order, with all latest improvements. Address JOHN S. MACBETH, Equitable Building, Denver, Colorado.

Here is our new Jack-head Miners' Sinking Pump.

Just the thing for muddy water.

Hardly ever needs repacking.

Send for our new catalogue, entirely about pumps.

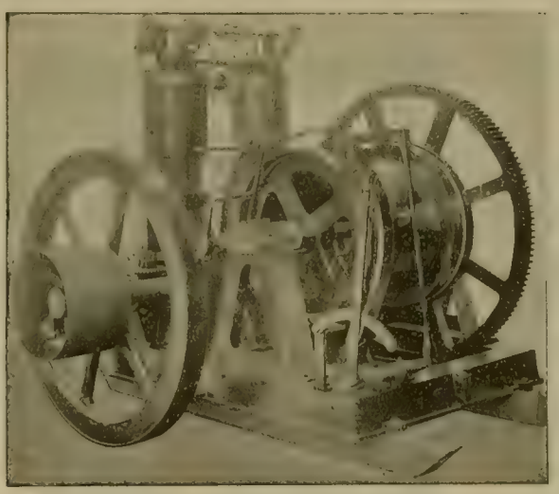
W. T. GARRATT & CO.
Cor. Fremont and Natoma Sts.
SAN FRANCISCO, CAL.

THE GOLD and SILVER EXTRACTION COMPANY, OF AMERICA, LTD.
CAPITAL, - $550,000.
The Original Cyanide Process.
SIMPLE. RELIABLE. ECONOMICAL.
TRADE MARK.

(M'ARTHUR-FORREST PROCESS.)
Gold Medal, Columbian Exposition, 1893.
MINE OWNERS and others having Refractory and Low Grade Gold and Silver Ores and Tailings should have their material tested by
The MacArthur-Forrest Cyanide Process.
Samples assayed and fully reported upon. Particulars upon application.
Advisory Board in the United States: Geo. A. Anderson, General Manager; Hugh Butler, Attorney; W. S. Ward; J. Stanley Muir, Technical Manager.
OFFICE: McPHEE BUILDING, DENVER, COLORADO.

INVENTORS, Take Notice!
L. PETERSON, MODEL MAKER,
226 MARKET ST., N. E. Corner Front (Up Stairs), SAN FRANCISCO. Experimental machinery and all kinds of models. Tin and brasswork All communications strictly confidential.

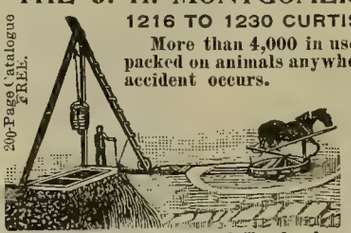
Improved Mining Hoist.



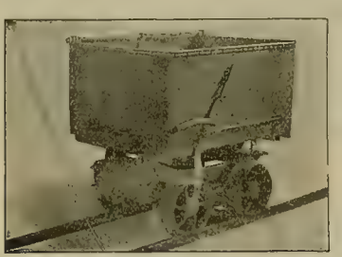
THE
Golden Gate Gas Engine
THE MOTIVE POWER.
Will Raise More Ore at Less Cost Than Any Other.
MANY IN USE
Giving Satisfaction.
Built for any Capacity and for any Purpose.
Pumping Water, Propelling Boats, Hoisting Ore, Machine Shop Power Etc.
Send for Particulars and Catalogue.

ADAM SCHILLING & SONS, 211 & 213 MAIN STREET, SAN FRANCISCO, CAL.

THE J. H. MONTGOMERY MACHINERY COMPANY.
1216 TO 1230 CURTIS ST., DENVER, COLO., U.S.A.
20g-Page Catalogue FREE.



More than 4,000 in use. Made of wrought iron and steel. Can be packed on animals anywhere. The deadlock holds the load when an accident occurs.
Price of One-Horse Whim, complete, with shieves..... $90.
Two-Horse Whims, complete, with shieves..... $150.
Pumping Attachment with Pipe for either..... $40.
Blower Attachment with Pipe for either..... $30
Also Four, Eight and Twelve-horsepower Whims.



Side-Dumping Ore Car,
All Steel Construction,
WITH ANACONDA SELF-OILING WHEELS AND AXLES.
THE BEST CAR BUILT.
Cars Built to Meet Any Requirements.
American Engineering Works,
204 Dearborn St., Chicago, Ill.

Utah Mines.
The Utah mining camps are fast forging to the front. THE TINTIC DISTRICT, BINGHAM, PARK CITY, MERCUR, LA SAL AND GOLD MOUNTAIN are all located on the line of the
RIO GRANDE . . .
WESTERN RAILWAY.
Two trains daily from Denver via Denver & Rio Grande or Colorado Midland and RIO GRANDE WESTERN. For pamphlets, etc., write
F. A. WADLEIGH,
General Passenger Agent, SALT LAKE CITY.

QUARTZ SCREENS
A specialty. Round, slot or burred slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American planished Iron, Zinc. Copper or Brass Screens for all purposes. CALIFORNIA PERFORATING SCREEN CO., 145 and 147 Beale St. S. F.

HUNDREDS ARE NOW SEEKING THE

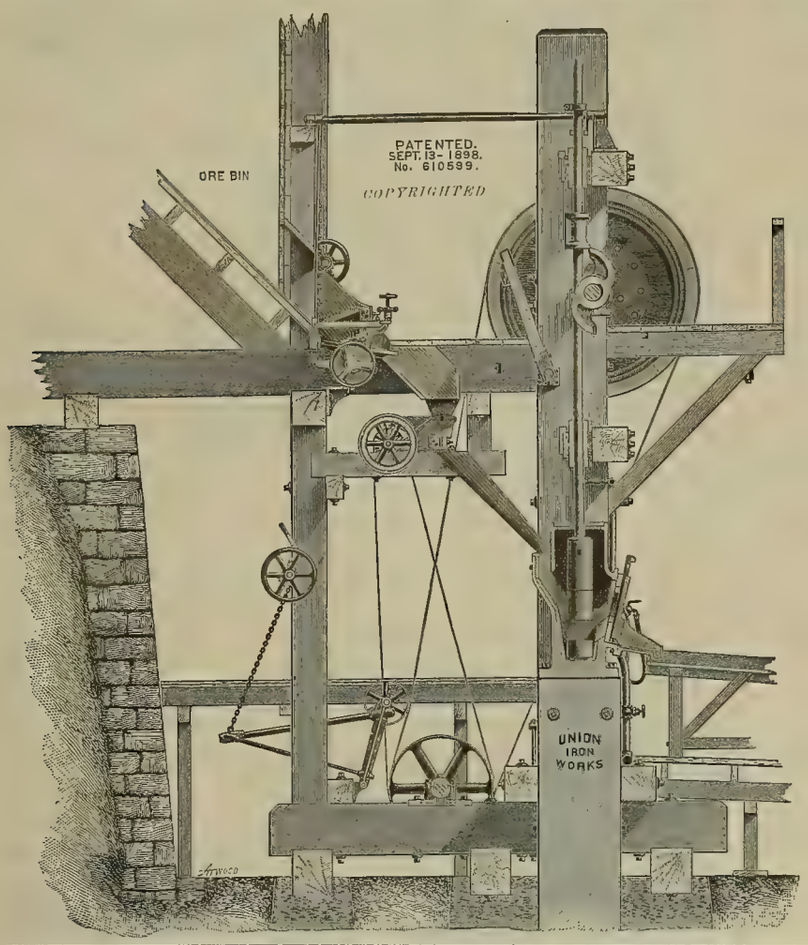
DIAMOND DRILL
FOR SALE.
OR CAN BE HIRED, TOGETHER WITH EXPERT TO OPERATE IT.
Apply to J. A. MURRAY, care of Risdon Iron Works, San Francisco.

UNION IRON WORKS,

222 Market Street, San Francisco, Cal.



THIS ILLUSTRATION

Shows our patent Improved Stamp Mill, with Secondary Crusher, which increases the capacity of the ordinary stamp battery from 25 to 30 per cent.

We respectfully invite the attention of those contemplating the erection of new mills to this practical improvement.

For particulars address

UNION IRON WORKS,

222 MARKET ST., SAN FRANCISCO, CAL.

MILL AND FACTORY POWER.

We supply it in the most economical form, namely, the "Westinghouse System" of electrical transmission, by means of which a distant water fall may be made to furnish cheap and unfailing power for your mill or factory. Its introduction makes poor properties valuable. Full information upon application.

Westinghouse Electric & MFG. CO., Pittsburg, Pa.

and all principal cities in United States and Canada.

MINE BELL SIGNALS.

Adopted, Used and in Force in Accordance with State Law.

FOR the convenience of our readers in the mining counties we print in legal size, 12x36 inches, the Mine Bell Signals and Rules provided for in the Voorhies Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We furnish these Signals and Rules, printed on cloth so as to withstand dampness. **50 Cents a Copy.**

MINING AND SCIENTIFIC PRESS, 330 Market St., San Francisco, Cal.

TANGENTIAL WATER WHEELS

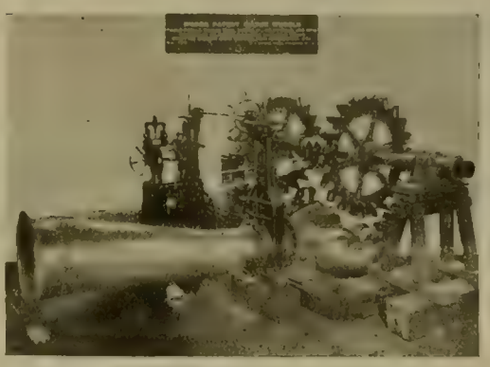
Manufactured by

RISDON IRON WORKS,

SAN FRANCISCO.

We build Water Wheels for any head and for any power. Complete electrical power generator wheels a specialty. Large wheels up to 50 feet diameter for driving compressors.

Send for Catalogue No. 4.



See those wires -- how they interlock? Note the smooth surface also. No displacement of wires in any event. Gives three times the service of other cables, and adds correspondingly to the life of the rolling stock.

DEWEY, STRONG & CO'S PATENT AGENCY.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American reports, with full copies of U. S. Patents since 1872. All worthy inventions patented through DEWEY, STRONG & CO.'S Patent Agency will have the benefit of a description in the *Mining and Scientific Press*. We transact every branch of patent business, and obtain patents in all countries which grant protection to inventors. The large majority of U. S. and foreign patents issued to inventors on the Pacific Coast have been obtained through our agency. We can give the best and *most reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and circulars free.

THE JOHNSTON CONCENTRATOR.

DURABILITY, CAPACITY AND SIMPLICITY : : ARE ITS ESSENTIAL POINTS. : :

SAVES MORE VERY FINE SULPHURETS THAN ANY OTHER CONCENTRATOR MADE.

The Johnston Concentrator is slung with arms from above on an angle, giving it the oscillating motion that makes it a perfect machine. This undulating motion immediately settles the sulphurets, retaining all amalgam, leaving sulphurets very clean, one 6 ft. Johnston doing the work of two 4-ft. belt mach'nes.

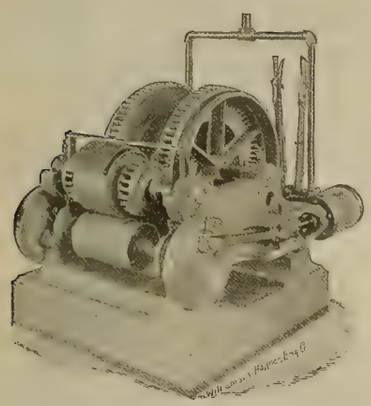
Hoisting from the 2600-foot level with



..Our Baby Hoist..

A remarkable record--don't you think?

READ WHAT THE SUPERINTENDENT OF COLORADO'S DEEPEST MINE SAYS:

THE GEYSER MINING AND MILLING CO., SILVER CLIFF, COLO.

The Hendrie & Bolthoff M'f'g & Supply Co., Denver, Colo.—GENTLEMEN: It may be of interest to you to know that we are now down 2600 feet with your Baby Hoist (4x6 Double Cylinder) which we purchased some time since. With this engine we are now handling the rock and ore broken by three shifts of four men each, and have had no difficulty whatever in so doing.

This engine stands in our 2400-foot level and is hoisting from the 2600-foot level. It is operated by air.

Very truly yours, W. J. ELMENDORF, Superintendent.

St. Valentine's Day, 1899.

We are selling these on a guarantee to hoist 1000 pounds 200 feet per minute from a depth of 350 feet.

(SEE PAGE 333.)

GATES FINE CRUSHER.

The result of ten years' solid work. Success at last. What we wanted, and the public demanded, was a Gates Gyratory Rock and Ore Breaker (always adjustable and indestructible) so modified in design as to make one-half-inch product from three-inch sizes, rapidly and cheaply. The H Fine Crusher will do this work. It takes the place of expensive big rolls and often prepares ore, without further crushing, fine enough for coarse concentration or cyaniding. In any event, it is the greatest and best intermediate machine between the coarse breaker and the pulverizer.

An Improvement in Modern Stamp Mill Practice.

GLOBE BATTERY STEM GUIDE.

PATENTED AUGUST 24, 1897.

RIGID. SIMPLE. DURABLE. EFFICIENT. ECONOMICAL.

Effect a Saving in Friction Losses. No Trouble to Install. No Alterations of Mill Necessary. No Keys or Wedges to Adjust.

Manufactured only by GLOBE IRON WORKS, STOCKTON, CAL., U. S. A.
Manufacturers of All Classes of Mining Machinery. Estimates Furnished.

OFFICE OF WILDMAN GOLD MINING COMPANY. SUTTER CREEK, CAL., June 28, 1898.

Globe Iron Works, corner Main and Commerce Streets, Stockton, Cal.—GENTLEMEN: Replying to your inquiry about the Globe Patent Battery Stem Guides furnished us by you last fall, will say that you supplied us with Guides enough for ten stamps of the Wildman Mill. These Guides have been in constant use for the past eight months, and so far **do not show any wear either on the Guides or the Stems.** They are more convenient than any Guide I ever handled, and much time is saved with them in changing stems, etc. The Guide can be set so close you always get a fair blow on your dies, and the use of these Guides materially increases the crushing capacity of your batteries. **It is our intention to replace all of our Guides with those of your make,** and I cheerfully recommend them to any one desiring a good, serviceable and economical Guide. Very truly yours, JOHN ROSS, JR., Superintendent.

TURBINE AND CASCADE WATER WHEEL

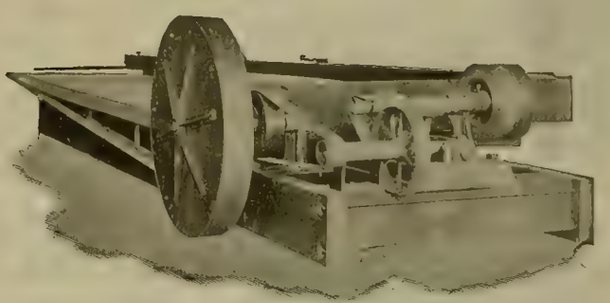
WHITE, ROGERS & CO., Consulting Engineers and Millwrights,

OFFICE, 306 PINE STREET, - - SAN FRANCISCO, CAL.

Sole Pacific Coast Agents and Builders of the Celebrated

WILFLEY CONCENTRATOR.



The Wilfley Table is fully covered by U. S. patents Nos. 580,338 and 590,675. Infringements will be prosecuted to the full extent of the law.

PRICE, $450, F. O. B., San Francisco.

One of these machines will take the place of two or three belt concentrators of any style and do very much better work.

Some Practical Reasons Why the Wilfley Concentrator Should Be Used in Gold Mills:

1. It will successfully handle three or four times more material than any belt Concentrator made, without exception.
2. It will save more sulphurets in proportion while so doing, and catch any float gold, amalgam or quicksilver which may escape from mortars or plates.
3. It will make cleaner and much more valuable concentrates, thus saving useless expense for transporting valueless material, as also extra cost for treatment.
4. It requires little or no attention when once adjusted and no expert is required to either adjust or run the machine.
5. It will save much expense in power and room, and the first cost of a mill requiring concentrators.
6. It has no expensive belts to crack and wear out, nor complicated machinery to keep in repair.
7. It is the only sensible plan of concentration, as any kind of material can be worked, which is not true of any style of belt machine.

SEND FOR CIRCULARS.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address **DEWEY, STRONG & CO., Patent Agents, 330 Market St., San Francisco, Cal.**

WOODBURY'S IMPERIAL CONCENTRATING TABLE.

THE Imperial Concentrating and Amalgamating Table is the latest invention of Mr. Geo. E. Woodbury, whose fame as one of the pioneer concentrator builders is world wide, machines of his manufacture being in general use in every country on the globe where the milling of ores is carried on. This Table is, however, built on entirely new lines, differing materially from either the well-known belt or bumping table types of concentrators.

Market Reports.

SAN FRANCISCO, March 23, 1899.

SILVER. — London, 27⅞d; New York, 59½; San Francisco, 59½; Mexican Dollars, 47⅛@48. New York exchange, sight, 12½; telegraphic, 15 cents premium.

Every steamer sailing from Australia has on board a large amount of gold for San Francisco. The amount of gold to come from Australia is estimated by bankers here at nearly $25,000,000.

LEAD. — New York reports "barely steady," $4.40 bid, $4.42½ asked; brokers' price, $4.20.

Local, pipe, 7¼@7½c; sheet, 7¼@8¼c; pig, 7c; bar, 7½c.

COPPER. — New York reports Lake dull and nominal; $16.75 bid, $17.25 asked; brokers' price, $17.50. Local, bar, 24c per lb.

IRON.—American, soft, $22@24 per ton; Scotch, $27. Local bar, 2½c per lb.

TIN.—Pig, 30c per lb.; Bar, 35c. New York reports firm, $23.85 asked.

ANTIMONY.—In San Francisco 1000 pounds and upwards, 10c net; 300 to 500 pounds, 11c; less than 100 pounds, 15c.

BABBITT METAL.—No. 3, 8½c.

QUICKSILVER.—Local, $42.50@43; export, $39@39.50; carload lots, special rates.

The News Bureau, published at Boston, where the majority of the stock of the California quicksilver mining companies is held, says the companies' statements for the three months ended Feb. 28 show as follows:

	New Idria.	*Napa.*	*Ætna.*
Gross.....	$43,800	$65,700	$35,405
Op. ex.....	20,856	32,931	20,954
Net.....	22,943	32,768	14,450
Dividend....	20,000	20,000	10,000
Surplus....	2,943	12,768	4,450

"The present dividend on Napa makes a total of $1,000,000 paid to stockholders. The quicksilver market is very strong at $44 per flask. This is an advance of $10 since 1894. Consumption has been increasing while production has fallen off materially. This advance in price means additional net earnings to the Napa of $70,000 per year, Ætna $35,000 and New Idria $45,000."

POWDER.—F. o. b., San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15¼c; less than one ton, 17¼c. No. 1* 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11½c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2* 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

FUSE.—Triple tape, $5.10 per 1000 feet; double tape, $4.35; single tape, $3.45; Hemp, $3; Cement No. 2, $4.35; Cement No. 1, $3.45.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9.

COAL.—San Francisco coast, yard prices:

Wellington	$8 00	Coos Bay	$5 00
Seattle	6 00	Southfield	7 50

Cargo lots, Eastern and foreign:

Wallsend	$ 7 50	Cumberland	$ 9 00
Brymbo	7 50	Cannel	9 50
Pennsylvania, hd..	14 50	Welsh Anthracite.	12 50
Scotch	8 00	Rock Springs	7 60

COKE. — Foreign, $13; domestic, $12 per ton.

CHEMICALS. — Cyanide of potassium, jobbing, 32 @ 33c per lb.; carloads, 30c; in 10-lb. tins 37c; sulphuric acid, 2c per lb. 66% B.; soda ash, $1.60 per 100 lbs. 58%; hyposulphite of soda, 2¾c per lb.; blue vitriol, 4½c per lb.; borax, refined, 5@6c per lb.; chlorate of potash, 9½@10c; roll sulphur, 2¾c; alum, $1.90@2.00; flour sulphur, French, 2¼@2½c; California refined, 1½@1¾c; nitric acid, in carboys 8c per lb; caustic soda, in 10-lb. tins 15c per lb.; Cal. s. soda, bbls., 65c; sks., 60c ℔ 100 lbs; chloride of lime, spot, 2.10 @2.25c; saltpeter, 15c; chlorate of potash, 25c; caustic potash, 12c.

CANDLES.—Electric Light Candles—6s, 16 oz., 8¼c; 6s, 14 oz., 7¼c; 6s, 12 oz., 5½c; 6s, 10 oz., 5½c; Granite (Mining) Candles—6s, 16 oz., 9¼c, 6s, 14 oz., 8¼c; 6s, 12 oz., 7½c; 6s, 10 oz., 6½c. Paraffine Wax Candles—1s, 2s, 4s, 6s, white, 10c; colored, 11c.

NAILS.—List per keg: No. 20 to 60d, wire, $3.10; cut, $3.00; 10 to 20d, wire, $3.15; cut, $3.05; 8d, wire, $3.20; cut, $3.10; 6 and 7d, wire, $3.30; cut, $3.20; 4 and 5d, wire, $3.40; cut, $3.30; 3d, wire, $3.55; cut, $3.45; 2d, wire, $3.80; cut, $3.60. In carload lots, 10c per keg less.

OILS.—California Castor, pure, cs., $1.08 per gal.; bbl., $1.03; pure No. 2, cs., 85c; bbl., 80c; Baker's AA Castor Oil, in case lots of 200 gals. and upward, $1.15; less than 200 gals., $1.10; in bbls., 4c per gal. less than case; Baker's Crystal, $1.40; China Nut, 50c; Linseed, strictly pure, boiled, bbl., 54c; cs., 59c; raw, bbl., 52c; cs., 57c; lots of 5 bbls., 1c less; Lucol, boiled, bbl., 49c; cs., 54c; raw, bbl., 47c; cs., 52c; lots of 5 bbls., 1c less. Kerosene—Pearl, cs., per gal., 17½c; Astral, 17½c; Star, 17½c; Eocene, 19½c; Extra Star, 21½c; Elaine, 22½c; Water White, bulk, in tanks, 11½c; Mineral Seal, iron bbls., 21c; wooden bbls., 23½c; cs., 26c; Mineral Sperm, 27c; Deodorized Stove Gasoline, bulk, 13c; do., cs., 18c; 86 deg. Assessment Notices.

EUREKA CONSOLIDATED DRIFT MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Forest Hill Divide, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 9th day of March, 1899, an assessment (No. 17) of one-half of one cent per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 1209 Claus Spreckels building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 11th day of April, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 28th day of April, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

J. J. CRAWFORD, Secretary.

Office—1209 Claus Spreckels building, San Francisco, California.

BEST & BELCHER MINING COMPANY. Location of principal place of business, San Francisco, California; location of works, Virginia District, Storey County, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the seventh (7th) day of March, 1899, an assessment (No. 66) of ten (10c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, Room 33 Nevada Block, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the tenth (10th) day of April, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the second (2nd) day of May, 1899, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

M. JAFFE, Secretary.

Office—Room 33 Nevada Block, No. 309 Montgomery street, San Francisco, California.

MARINA MARSICANO GOLD MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Sunny Hill, Shasta County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 11th day of March, 1899, an assessment (No. 18) of 5 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, 217 Sacramento street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 17th day of April, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 8th day of May, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CHARLES BOVONE, Secretary.

Office—217 Sacramento street, San Francisco, California.

NATIONAL CONS. MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Rich Gulch, Shasta County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 20th day of March, 1899, an assessment (No. 6) of ten (10) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 773 Mission street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 8th day of May, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on THURSDAY, the 1st day of June, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

G. W. FLEISSNER, Secretary.

Office—773 Mission street, San Francisco, California. Office hours from 1 to 3 P. M.

HEAD CENTRE CONSOLIDATED MINING COMPANY.—Location of principal place of business San Francisco, California; location of works, Tombstone Mining District, Cochise County, Arizona.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 20th dayof March, 1899, an assessment (No. 7) of twenty (20) cents per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, No. 310 Pine street, rooms 15 and 17, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 2nd day of May, 1899, shall be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 29th day of May, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

J. W. PEW, Secretary.

Office—No. 310 Pine street, rooms 15 and 17, San Francisco, California.

DELINQUENT SALE NOTICE.

ORLEANS MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Grass Valley, Nevada County, California.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 8, new series) levied on the 8th day of February, 1899, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Cert.	No. Shares.	Amt.
Frances Pierce	226	215	$15 05
John T. Thornton	154	50	3 50

And in accordance with law, and an order from the Board of Directors, made on the 20th day of March, 1899, so many shares of each parcel of such stock as may be necessary will be sold at public auction, at the office of the company, room 10, No. 324 Pine street, San Francisco, California, on WEDNESDAY, the 12th day of April, 1899, at the hour of 2 o'clock P. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

GEO. P. THURSTON, Secretary.

Office—324 Pine St., San Francisco, California.

JAMISON MINING COMPANY, Rooms 50 and 54, No. 120 Sutter street, San Francisco, California, March 21st, 1899. SEMI-ANNUAL DIVIDEND NO. 3.

At their meeting of March 21st, 1899, it was resolved by the Board of Directors of the Jamison Mining Company to pay to the stockholders of the company from the surplus funds in the treasury, a dividend of Eleven (11) Cents on Seven Hundred Dollars ($11,700), being three (3) cents per share on the capital stock of the company.

The dividend will be payable at the office of the company on the 15th day of April, 1899, to all stockholders of record on the 5th day of April, 1899. Transfer books will be closed at the close of business on the 5th day of April and reopened on the morning of the 17th of April, 1899.

Mining and Metallurgy.

The latest and best books can be had from the Book Department of the MINING AND SCIENTIFIC PRESS at best prices. ALL BOOKS SENT POST-PAID. Following is a partial list:

ASSAYING:—PART I—GOLD AND SILVER ORES.

Third edition; Rewritten and Improved by the Author, C. H. Aaron; 130 pages, illustrated....$1

ASSAYING:—PARTS II & III—GOLD AND SILVER BULLION, LEAD, COPPER, TIN, ETC.

Latest edition; 161 pages, illustrated, cloth. Much of the original text replaced by new matter....$1 75

ROASTING OF GOLD AND SILVER ORES AND THE EXTRACTION OF THEIR RESPECTIVE METALS WITHOUT QUICKSILVER:

Second edition; Guido Kustel, M. E.; 156 pages, with illustrations of furnaces, supplements and working apparatus....$3

PRACTICAL TREATISE ON HYDRAULIC MINING:

By Aug. J. Bowie, Jr. On the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on heavy grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc....$5

PRACTICAL HYDRAULICS:

A book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers and Irrigators. By P. M. Randall. Contains useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulæ, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules and tables are prepared. Is specially applicable to the Pacific Coast....$2

MODERN COPPER SMELTING:

E. Dyer Peters, Jr. Eighth edition. Rewritten and enlarged. Profusely illustrated....$5

STAMP MILLING OF GOLD ORES:

By T. A. Rickard, M. E. An actual record of milling practice in this and other countries. Deals with the erection and management of mills, and contains many helpful suggestions. Well illustrated. Cloth....$2 50

MINERS' POCKETBOOK:

A reference book for miners, mine surveyors, geologists, mineralogists, millmen, assayers and metallurgists. By C. G. W. Lock. 472 pages, illustrated, flexible leather....$5

MANUAL OF MINING:

For the use of Mining Engineers and Technical Schools. Treating of Preparatory and Exploratory Work, Methods of Mining, Hoisting Machinery, Pumping, Ventilation Shafts, Tunnels, Blasting, Timbering, etc., etc. By Prof. Magnus C. Ihlseng, E. M., Ph. D. Third, revised and enlarged, edition. 548 pages, 8vo., cloth....$4

THE METALLURGY OF GOLD:

By M. Eissler. Profusely illustrated....$5

THE EXPLORER'S AND ASSAYER'S COMPANION:

Third edition. By J. S. Phillips. A practical exposition of the various departments of Geology, Exploration, Mining Engineering, Assaying and Metallurgy. An exceeding valuable work....$6

CYANIDE PROCESSES FOR GOLD AND SILVER ORES:

By E. B. Wilson, E. M....$1 50

SKELETON MINING REPORT:

Of great practical value to miners and mine owners in making a comprehensive report on mining properties. Useful and convenient to mining engineers as a field notebook. Price, postpaid....50c

QUARTZ OPERATOR'S HANDBOOK:

By P. M. Randall....$2

ALLOYS:

Thurston, 2nd edition....$2 50

ASSAYING:

Furman, 4th edition....$3

HIGH EXPLOSIVES:

Eissler....$4

GOLD ORES:

Treatment of: O'Driscoll....$2

MINERALOGY:

Brush & Penfield, revised edition, $3 50; Dana, 6th edition, $12 50; Dana, for beginners, $1 50; Dana, Mineralogy and Petrography, 12th edition....$2

MINERALS:

"How to Study Them," Dana, 2nd edition, $2; Dana, American locality of mineral, 6th edition....$1

MINING:

Ihlseng, from lectures in Colorado School of Mines....$4

ORE DEPOSITS:

Phillips, revised edition by Louis....$7

METALLURGY:

Eggleston, Silver, Gold and Mercury, 2 vols.$15

TUNNELING:

Blasting, Timbering, Air Drilling, etc.; 1000 illustrations; Drinker, 3rd edition....$25

CHLORINATION PROCESS:

E. B. Wilson....$1 50

HYDRAULIC AND PLACER MINING:

E. B. Wilson....$2

GEOLOGY:

Emmons, $1 50; Scott, $1 90; Le Conte, revised edition, $4; Dana, 4th edition....$5

IRON AND STEEL:

Thurston, 6th edition....$3 50

LITHOLOGY:

Williams, 2nd edition....$3

LIEBER'S CODE:

Bound in leather....$3

P&B BUILDING PAPER

The walls of a house are built for protection. If the sun and weather open up the sheathing, the rain or the air will get in and cause discomfort and doctor's bills. To prevent this the architect or builder uses building paper. There are many kinds, but only two classes—the poor and the good. P & B PAPER is good—the best. It is very strong, odorless, waterproof and airproof, and will not rot. Ask your dealer for samples, or write us for them. We are the makers.

PARAFFINE PAINT CO.,
San Francisco,
116 Battery St.

STRICTLY C. P. Acids & Ammonia

— MANUFACTURED BY —

THE WESTERN CHEMICAL COMPANY,
DENVER, COLO.,

For Laboratory Use and Fine Chemical Work. Also Commercial Acids, Blue Vitriol, etc., etc.

Cyanide Potassium—99% pure, Beckton brand.
Chloride Lime—Best English in casks and drums.
Zinc Dust—Best heavy quality.
Potash Permanganate—Pure quality.

AND ALL OTHER CHEMICALS.

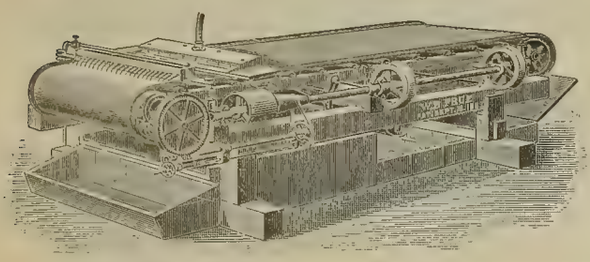
FOUR and SIX-FOOT FRUE VANNERS

With Brownell "Patent Lip" Flange Belts.



STANDARD MACHINE OF THE WORLD.

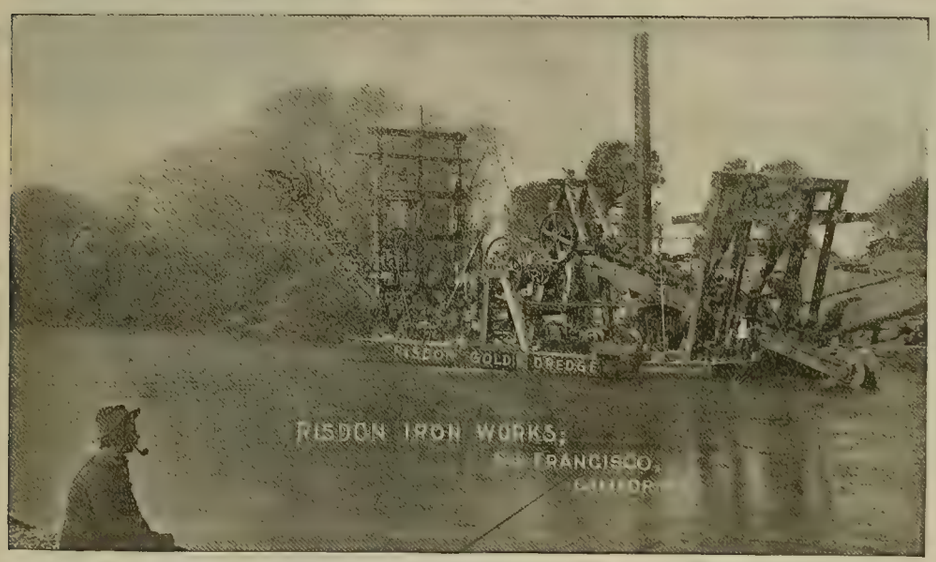
When a Concentrator like the Frue Vanner has been on the market nearly two decades, and the sales have constantly increased, it is safe to say it is the "Standard Machine of the World." More Frue Vanners have been sold during the last twelve months than for the same period at any time during the history of the machine. Practical mining men in all parts of the world where mining is carried on will testify as to its merits. It is the "standard" which all competitors are trying to imitate.

The results obtained by this machine are the "acme" of concentration, and several cheap and untried machines that have lately come on the market compare by it. The manufacturers will tell you that they are "just as good, and cheaper," etc. The facts are that no other concentrator made has an equal capacity, or will yield as clean a concentrate with as small loss in the tailings as the Frue Vanner. The amount saved from the lower first cost of an inferior machine counts little in the year's results, when compared with the increased output from a Frue. This machine not only gives better results at both ends of the belt (i. e., clean product and poor tailings), but is operated at less expense and requires less attention than any other machine on the market. At the Alaska-Treadwell mine, where they have ordered over 350 Frue Vanners, one man attends 48 machines for 12-hour shift.

FOR DESCRIPTIVE PAMPHLETS, ADDRESS

J. S. BROWNELL, Western Agent FRUE VANNING MACHINE CO.,

132 MARKET STREET, (Successor to Adams & Carter.) SAN FRANCISCO, CAL.



RISDON IRON WORKS,

—MANUFACTURERS OF—

Gold Dredging Machinery

And COMPLETE EQUIPMENT for Placer Mines

OUR SPECIALTY.

We build **GOLD DREDGES COMPLETE IN RUNNING ORDER** to handle 2500 cubic yards per day at a cost of 3 cents per cubic yard. We excavate 50 feet below water, 20 feet above water and handle boulders up to one ton weight.

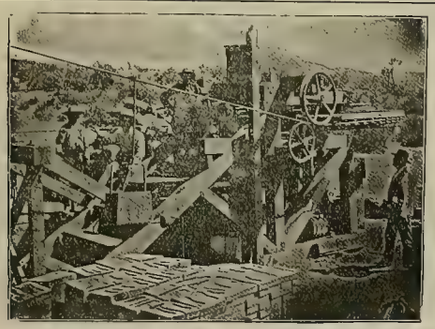
Send for Dredging Catalogues Nos. 15 and 16.

WE ALSO BUILD

All kinds of Mining, Milling, Concentrating, Pumping, Air Compressing, Hydraulic, Water Wheel and Hoisting Machinery.

EVANS HYDRAULIC GRAVEL ELEVATORS.

We publish sixteen catalogues. Write for one in the line you are interested in.



THE HALLIDIE ROPEWAY

For transporting Ore, Fuel, Merchandise, etc., in bulk or in packages. SIMPLE, ECONOMICAL, INEXPENSIVE, PRACTICAL.

LOADS MECHANICALLY. DUMPS AUTOMATICALLY. Send for Ropeway Pamphlet No. 20.

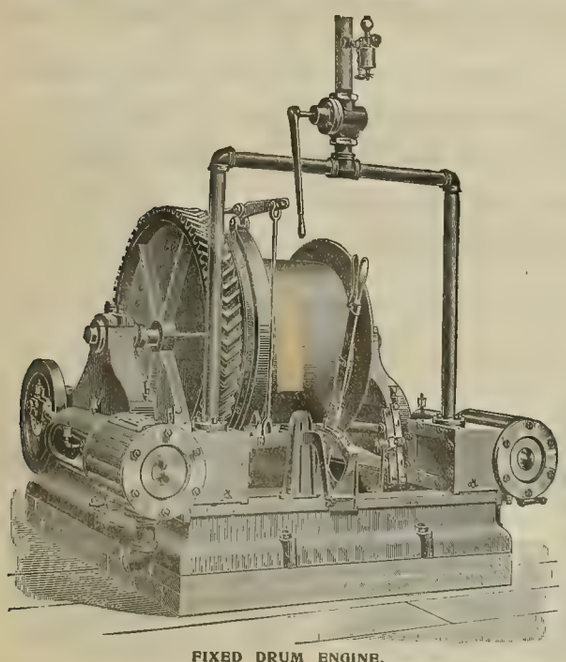
THE CALHOUN EXCAVATOR.

A COMBINED POWER-SHOVEL AND CABLEWAY. .....Ask for Circular.....

Cableways, Double Rope Tramways, Wire Rope Transmissions, Incline Planes, Logging Machinery, Suspension Bridges,

DESIGNED, FURNISHED, ERECTED. Write for Estimates.

CALIFORNIA WIRE WORKS, - 330 Market St., San Francisco, Cal.



FIXED DRUM ENGINE.

PARKE & LACY CO.,

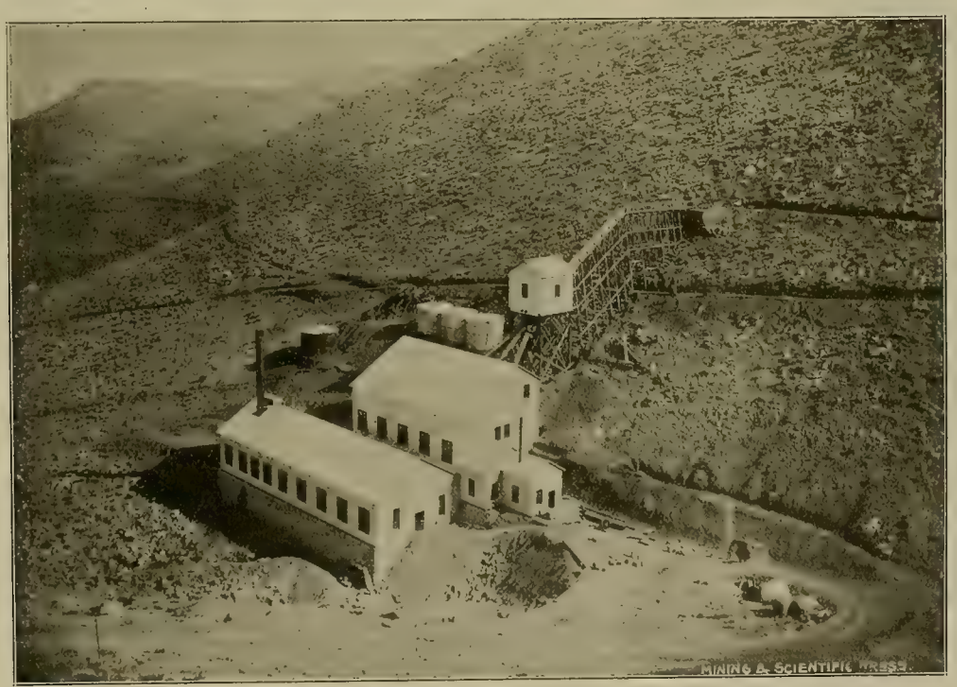
The Yellow Aster Mine, Randsburg, Cal.

As an illustration of what may be accomplished on even the deserts of California the rapid rise of the Yellow Aster mine at Randsburg, Kern county, California, from a prospect to a place in the ranks of California's producing mines is a striking and instructive example. Isolated at first from communication with the outside world; situated on a rugged hill in a treeless and waterless desert; without the backing of capital, the owners have surmounted all obstacles and shown what may be accomplished by enterprising men in the face of many obstacles. The Yellow Aster is the name covering a group of several claims lying upon the summit and sides of a ridge between the towns of Johannesburg and Randsburg, situated about one mile apart. The former place is now connected by rail with the Atlantic & Pacific railroad at Kramer. The country rock of the district is described as schistose, having a northeast strike and northwest dip. Numerous dykes traverse this formation and large veins of white, barren quartz outcrop in many places in the district. The surface of the ground is strewn with cobbles and boulders of andesite, derived probably from the large masses of this rock lying to the northward and capping the hills in that direction.

The Yellow Aster mine lies between two large dark-colored dykes, which being harder than the rocks in which they occur, stand several feet above the surface. These dykes are about 600 feet apart and may be seen crossing the ridge obliquely for several hundred feet. On the summit of this ridge is a large mass of gold-bearing rock from which veins extend in several directions. Some portions of the ridge seem to be a network of veins, the Trilby tunnel, for instance, having cut twenty-six separate veins of various sizes in a distance of 350 feet. A great amount of work has been done on the various veins, but the systematic development which must mark the mine of the future is only just being outlined.

The mine was discovered by dry-gulch prospectors who gradually worked up the gulch, and finally their work took them to the gold-bearing veins. The news spread rapidly and other prospectors came to the district, and new finds were of almost daily occurrence. Eventually custom quartz mills were built at neighboring springs, eight to sixteen miles distant, and to these the miners of the district hauled their ore in wagons and had it crushed at heavy expense, and it required a high-grade ore to pay these charges and leave a profit; but of such are these desert mines. The Yellow Aster mine sent ore to Garlock mill, several miles distant. Later, upon completion of the railroad from Kramer to Johannesburg, a large mill was built near Barstow on the Mojave river, and many of the mines of the district shipped their ores to that point by rail for treatment, making a short haul to the railroad terminus with wagons. The Yellow Aster mine for a long time shipped sixty tons of ore to Barstow daily. A few days since the Union Iron Works of San Francisco completed a modern 30-stamp gold mill which is built on the company's property in the canyon, above which the mines are located, as shown in the accompanying illustration. The construction and successful operation of a large quartz mill in this desert region necessitated the solution of two important economic problems—water and fuel, neither of which were apparently obtainable in any considerable quantity within many miles of the mines. The company purchased Skillings wells, six miles distant, sunk a shaft there and built a pumping station, laid a pipe line and are now able to furnish about 100,000 gallons of water daily to the mine and town. The water is raised from the shaft about 90 feet and pumped into a tank having a capacity of 125,000 gallons. From the tank a tandem compound duplex pump forces the water through a pipe line six miles long with a lift of 500 feet at a rate of 9000 gallons per hour. At the pump station are two men who look after the plant and run it ten to twelve hours daily. The pumping engines are 40 H. P. The water is delivered at the mine into three tanks having an aggregate capacity of about 75,000 gallons. In this manner the water question was settled. The fuel problem was equally important, and after careful inquiry crude petroleum was determined upon as the most economical fuel under the circumstances, and this is obtained from the Los Angeles wells at a cost of $1 per barrel and is of superior quality, seemingly well suited to this use. The oil is delivered at the railroad terminal in car tanks holding 6000 gallons and hauled by wagon to a tank having a capacity of over 30,000 gallons, located some distance from the mill and 30 feet above the boilers. The fuel plant is provided with two pumps, but these are found unnecessary, the pressure afforded by the tank being found sufficient to feed the fuel as required. By this means steam is generated which furnishes the motive force for all the machinery at the mill. The stamps are run by a 12″x30″ engine; a separate 8″x10″ engine runs the breaker, and a third 10″x12″ runs an electric generator which supplies light for mine, mill and other buildings.

The mill is solidly constructed on terraces formed by building substantial retaining walls along the graded excavations. The structure is covered with corrugated iron. The mortar blocks are made from 28″x28″ timbers 14 feet long, set in pairs, and resting on a concrete foundation, being filled in with concrete. The 10″x16″ jaw crusher is set on a heavy frame of 12″x12″ timbers and wholly disconnected from the mill building, being under a separate roof. The cam floor of the mill is suspended by iron rods from the roof trusses of the building, thus affording more light than is found in many mills. The feeders are suspended, and the large space back of the feeders and underneath the ore bins is used as a storeroom for many articles required about the mill. The main line shaft passes back of the batteries underneath the feeder floor. The plate area is large and the ore is thus far free milling. In front of the mortars and above the plates is arranged a steel beam from which a bucket is suspended on travelers. When the mortars are to be cleaned this bucket may be moved and their contents shoveled into it and dumped into the clean-up barrel. The concentrator building is apart from the battery building though joining it. A glance at the illustration will show the advantage this affords in lighting the batteries. The ore is delivered to a chute which discharges in a bin above the breaker. From the breaker it goes to the bin in the mill having a capacity of 200 tons. Burr slot No. 7 screens are used, the capacity being four tons per stamp; 120,000 gallons of water are used daily which is more than is usually required, but is due to the dryness of the ore. The tailings pass into a reservoir, the overflow from which is pumped back and re-used. It is estimated a saving of 40% to 50% is thus effected. The cost of fuel is about 25 cents per ton of ore, and of water about the same, showing that after the first cost of plant it is less expensive than might be imagined. For the more thorough development and systematic operation of the mines the advisability of sinking a three-compartment vertical shaft is being considered.



THIRTY-STAMP MILL AT THE YELLOW ASTER MINE, RANDSBURG, CAL.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Thirty-Stamp Mill at the Yellow Aster Mine, Randsburg, Cal., 341. Asphalt Mine, Santa Maria, Cal., Asphalt Co., 344. Latest Mining and Metallurgical Patents, 347. Irrigation Scenes in Wyoming, 348. Plan of Ordinary Condenser; Section and Elevation of Condenser; Buying Water at a Condenser; Condenser at the Lake View and Junction Mine, Kalgoorlie, 349. The Crosshead and Bucket in Vertical Shafts, 351.

EDITORIAL.—The Yellow Aster Mine, Randsburg, Cal., 341. The Canadian Alien Act; The Eight-Hour Mine Law; Miners in the Philippines; Prospecting Company at Butte, Mont.; The Latest in Wireless Telegraphy; Americans in the Atlin Lake Country; Conclusion of "Alluvial Deposits of Western Australia;" Compressed Air for Rapid Transit; Annual Catalogues from Colleges; A New Form of Dissipation in the Klondike; "Taking in a Situation;" Contrast in Price of Boston's Copper Stock, 342.

MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 351-52-53.

THE MARKETS.—The Local Markets; Mining Share Market; Sales in San Francisco Stock Board, 366.

MISCELLANEOUS.—Concentrates, 343. The Genesis of Petroleum and Asphaltum in California, 344. A New Method for the Determination of Zinc; Experiences of a Working Miner, 345. Dredge Mining in California; Saving Fine Gold in Sluices; Results to Advertisers; The Crosshead and Trip Rope; Loss of Gold; A Correction; To Determine the Currents of the Arctic, 346. Latest Mining and Metallurgical Patents, 347. What a Mile a Minute Means to the Locomotive Making It; The Mule Must Go; Existence of Many Stars or Suns; Omission in the Patent Laws; Irrigation in Wyoming; The New Nernst Lamp; Fostering of the Mechanical Instinct; French Development of Wireless Telegraphy, 348. The Alluvial Deposits of Western Australia, 349. Hardwood Veneers; For the Advancement of Scientific Research; The Crosshead and Bucket in Vertical Shafts; Small Reservoirs; To Be Surpassed by an American Inventor; Restrictions upon Hydraulic Mining, 350. Industrial Notes; California Mining Incorporations; Commercial Paragraphs, 353. Personal; List of U. S. Patents for Pacific Coast Inventors; Notices of Recent Patents, 354. Recently Declared Mining Dividends, 366.

TWO INTERESTING FACTS.

In all the States of the Far West and the Pacific Slope, consisting of California, Oregon, Washington, Idaho, Montana, Wyoming, Colorado, New Mexico, Arizona and Utah, the largest circulation credited to any publication devoted to engineering and mining is accorded to the MINING AND SCIENTIFIC PRESS, a weekly, published at San Francisco, Cal.—*American Newspaper Directory.*

Among the engineering and mining papers in California, none has credit for so large a regular issue as is accorded to the MINING AND SCIENTIFIC PRESS, published weekly at San Francisco. In fact, it fully equals five times the combined issue accorded to all the others.—*American Newspaper Directory.*

JUDGING from the tone of the northern press, the Canadian alien act does not meet with universal favor in British Columbia, the merchants on the coast claiming that they have lost thousands of dollars by reason of it.

WHERE the eight-hour mine law has been introduced through legislative action mine managers have accepted the situation — and promptly reduced wages proportionately. In some cases the miners are taking steps to have the law repealed.

AMONG the U. S. troops in the Philippines are many miners, who have already organized a miners' union. When mustered out of service, doubtless some of these practiced prospectors will exploit and develop whatever mineral wealth is possessed by that region.

A NUMBER of men at Butte City, Montana, have incorporated a prospecting company with 5000 shares of a par value of $1 each, all of which has been subscribed. The stock is paid for in monthly installments. Work will be commenced under the direction of a competent manager in Idaho. This is an association organized for a definite purpose on a common sense basis, and is likely to lead to satisfactory results.

THE latest in wireless telegraphy is the stated success this week of the Marconi system in transmitting intelligence. The London *Times* of the 29th ult., printed a 100-word dispatch, the first press message of the kind, descriptive of successful sending of dispatches between England and France, thirty-two miles. Considerable technical description has appeared herein, and the method is presumably understood by our readers.

THE continued rush of Americans into the Atlin Lake country, Northwest Territory, in the face of the exclusion act, only illustrates the character of the American prospector, who is nothing if not an adventurer. He will risk a desperate chance on anything which holds the least promise of money or excitement. It is unnecessary to say that they cannot hold claims in British territory unless the law is repealed, which is scarcely to be expected, though since the passage of the law its bad effects are so apparent that many of the British Columbia papers are clamoring for its repeal.

IN this issue is concluded an interesting description of the "Alluvial Deposits of Western Australia," written by T. A. Rickard, State Geologist of Colorado, in which have been described the geological occurrence and the methods of exploiting the superficial gold-bearing deposits of that desert country. In California, Nevada and Arizona are found conditions almost, if not quite, identical with those described by Mr. Rickard, and miners who prospect in the desert regions of the Pacific coast might profit largely by a study of the conditions and methods of Australia. In California are numerous places where gold should be found under similar conditions, and there are instances of record where gold does occur under such conditions. In the Cargo Muchacho mountains gold was picked up on the surface which had been derived from veins in the vicinity without doubt. A few days ago gold was discovered in a superficial cemented gravel deposit near the St. Elmo mine, six miles south of Randsburg, Kern county, Cal., which is now being successfully worked. Gold has been picked up from the surface near Eagle mountain, in Riverside county, Cal., and in the Monte Negras hills, sixteen miles north of Eagle mountain; the gold-bearing veins run down to the edge of the desert wash and some of these veins are rich in gold. In one of these veins coarse pieces of gold, aggregating $1200, were dug out in a single day. Back of Ehrenburg, in Arizona, are local beds of gold-bearing conglomerate lying on the surface. And these conglomerates occur in so many other places that it is not unlikely that some others may be gold-bearing. The large beds of conglomerate near Goler and Red Rock, northwest of Randsburg, are not of this class—they being extensive, heavy-bedded shore deposits of a pre-existing inland sea or large lake, though these, too, are sometimes gold-bearing.

WITHIN the memory of living men no faster means of transit existed than in the days of Herodotus or the settlement of the valley of the Nile. By swift advance time and distance have practically been annihilated, and upon the heels of an announcement concerning projected advances comes the news of experiments demonstrating their practical success. The latest agent for motive power in rapid transit is compressed air. As in other lines of scientific progress improvement in one admits of advance in others. Though the utility of compressed air as a motive power has long been put into practical recognition and widely utilized, it is but recently that advances in the composition of structural material has admitted of further enlargement of its powers. Pressures heretofore impossible can now be handled with absolute safety. The result is the widening of the field for compressed air apparatus, and one of the first enlarged uses is in the building of automobiles. These "horseless carriages" are now propelled by steam, gas engine and electricity. Compressed air has further invaded this inviting field, and in several cities companies are organizing to build freight and passenger conveyances in which the motive power shall be compressed air. Already in New York city, for freight traffic, steel trucks weighing 8000 pounds and capable of carrying 20,000 pounds are building, the builders claiming that they can be run at an expense not exceeding half a cent per mile for power, and, by instantaneous changing at sub-stations, made available for any desired distance. The same company asserts its ability to run compressed air passenger cars from twenty-five to fifty miles without recharging.

ANNUAL catalogues from the principal colleges, universities and scientific schools of the country are frequently received and their favorable features observed. In several much is to be noted favorably, this being particularly so in the case of Cornell College, the Michigan Mining College at Houghton, Mich., and the Massachusetts Institute of Technology at Boston. The latter institution has a particularly noticeable feature that commends itself strongly to the practical man. In the thirty-fourth annual catalogue to hand is a register of graduates, occupying 100 pages, giving the names of those who graduated from 1868, and, if alive, their present occupation. To our mind that is the most interesting part of the 350 pages. According to the 100 pages of names and occupations, about 1900 who have graduated from that institution now fill positions of honor, trust or profit in nearly every walk of life, being more particularly prominent in mining engineering, mechanics and applied sciences, scattered all over the United States. This roll of renown adds dignity to the institution and sheds luster on its honorable record. It is a feature worthy of observation and reproduction elsewhere.

MANY statements are gravely made regarding miners and believed in by general readers. One is now traveling through the press regarding a new form of dissipation developed in the Klondike, viz., eating snow. It seems that when the Klondike miner has a well-developed thirst ordinary liquor fails to satisfy, and nothing but a riotous round of snow-eating satisfies him. From Eastern papers which would not under any circumstances vary from the frozen facts, it is learned that in the Yukon region "the snow is saturated with mineral vapor," which has a fatal fascination for the unhappy miner who yields to its insidious delights, and once having tasted of this mineralized snow nothing else will quench the inward desire for such strange and unhallowed stimulant. Deprived of his potations "he lies moaning for a mouthful of snow," and, when momentarily overlooked by his companions, seizes upon the fleecy covering of the adjacent landscape, "and gulps it down in huge handfuls." Further information is vouchsafed to the effect that after returning to lands less favored with snowfall the victim of this new form of Klondicitis yearns with an unutterable yearn for the scenes of his former wild debauches, and would fain return once more to indulge in his former orgies of consuming snow. It seems that a "red snow" which falls near Point Barrow is the favorite tipple of those depraved inebriates. These saddening statements will be read with regret by many who had hoped that the high price of ordinary intoxicants in that region would tend to diminish inebriety. From all accounts snow is plenty there and within reach of all, and in the general interests of temperance it is hoped that the assertions of the Eastern papers regarding the prevalence of the snow habit may not be wholly corroborated by the facts.

SUCCESSFUL business men feel a certain pride in their achievements, as they have a perfect right to, and with this success comes confidence and self-reliance, and it is doubtless this feeling of ability to "take in a situation" that leads men who have been successful in merchandizing or industrial pursuits to feel, when they determine to branch out into mining, that they are fully competent to handle the business without outside assistance. How many fortunes have been dissipated by unfortunate investments, which any professional mining engineer or practical miner would have "turned down" without hesitation! Even where ultimate success results, often serious errors have been made in the early career of the new-made mining man. The business of mining is not to be learned in a day. There are a thousand and one things to be investigated and considered, and when in successful operation contingencies often arise of the most perplexing character, which only experience can meet. Of course, all those who are new in the business do not undervalue the services of competent and experienced men, but there are monuments of folly all through the mining regions, which show that such mistakes are of very common occurrence. A large manufacturer or merchant would never think of engaging a mining engineer to conduct his own business. Why, then, should men reared to commercial life assume to take the place of the man who has spent the best part of his life in learning what he knows of his business?

SOME of the water is being squeezed out of Boston's inflated copper stocks. A contrast between the high prices of February and the lower prices of last month shows a shrinkage in selling value of over $60,000,000. The biggest reported drop was in Calumet & Hecla, from 895 to 705. Of course, the street and the mine have nothing in common, and the Calumet & Hecla property is as gilt-edged as ever.

Concentrates.

HUNGARIAN riffles lie lengthwise in the sluice box.

THE longest tunnel in the world is the Simplon, through the Alps—12¼ miles. The deepest artesian well is at Budapest—3140 feet.

WAGES in the Boise, Idaho, placer mines are $2.50 and $3 per day for miners; laborers, $2 and $2.25; board is $4.50 and $5 per week.

IN the States of California and Oregon about 1000 tons of "blue vitriol" are annually consumed. The trade price is about 4 cents per pound.

A 9 COLUMN description of the power plant of the Electrical Power Co. of Ogden, Utah, with seven illustrations, appeared in the issue of July 24th, '97.

THE mine salting case at Baker City, Or., resulted in a Scotch verdict, "not proven," though one of the men implicated—Griffin—made a written confession.

ELECTROPION fluid for putting in batteries is composed of water, 100 parts by weight; potassium bichromate, 16 ditto; sulphuric acid, 66°, 37 ditto; not to be used till cold.

ARTIFICIAL stone or concrete can not be made with silicate of soda. That silicate is sometimes used for drying the surface, but does not ordinarily enter into its composition.

THE meter is 39.37 inches in length. To reduce meters to yards, multiply by 1.094; to reduce kilometers to miles, divide by 1.6093; to reduce liters to gallons, divide by 3 78.

IN Arizona wages of employes at Clifton and Morenci, the two copper camps of Graham county, have been raised 10%; at Bisbee miners' wages have been raised to $4 per day.

SOUTHERN California miners are asked to meet at the Los Angeles Chamber of Commerce on the 29th inst. to form a southern California branch of the California State Miners' Association.

THE Arizona Legislature did not pass the proposed bullion tax. Governor Gage of California signed the bill repealing the Act of March 26th, '97, prescribing the manner of locating mining claims.

THE Arizona Legislature has passed a law exempting reservoirs and canals, and all other property used in the development of water for mining, manufacturing and development purposes, for fifteen years.

AT Slough Creek, near Barkerville, Cariboo, B. C., Mr. Hopp, the former manager, says that F. C. Laird, the present manager, is not able to get all the experienced miners he wants, though paying $5 per day of eight hours.

IT is not possible to state at present exactly what gold mine in California produced the most in '98, though it is believed that the total outputs of the Utica, in Calaveras Co., and the Golden Cross, in San Diego Co., did not differ greatly.

THE Central Pacific Co. has, after mature deliberation, decided to publish a chart showing fifty years rainfall in California. On Jan. 1st, '99, this paper published such a chart, a copy of which will be sent postpaid to any one asking for it.

WHILE rich deposits attract the most attention, it is the low-grade ore that ordinarily pays the best if in sufficient quantity to justify its treatment on a large scale—quantity, not quality, being the main requisite and the surest proposition.

AN unusual phenomenon is noted at the furnaces of the Mountain Copper Co. at Keswick, Cal., where, it is stated, while the sulphurets are being roasted swarms of flies live and breed in the smoking, burning piles, to such an extent as to annoy the workmen.

AT Denver, Colo., this week, in the U. S. District Court, Judge Hallett rendered a decision to the effect that aliens are not, under the laws of this country, entitled to recover damages from a corporation, company or employer for injuries sustained while in the employ thereof.

ELECTRICAL SIGNAL BELLS are no novelty in mines. In many mines in California and other gold mining States they are in use. If "Elex" has any improvement susceptible of patent and worthy of adoption he should go ahead. The requisite is to overcome friction and preserve necessary insulation.

TINSTONE, or cassiterite, is 79% tin and 21% oxygen, brown or black, and of brilliant luster when crystallized. It is usually found in grains or bean-shaped lumps, in both lode veins and placer deposits. The latter is the chief source of the Malay tin. No tin is mined in the United States at present.

WHERE tattooing on the skin has been done with some carbonaceous matter, the marks can be caused to go away by being first thoroughly rubbed with a salve of pure acetic acid and lard, then with a solution of potash, and finally with hydrochloric acid. Usually it is better to let the tattooing alone.

CRIPPLE CREEK, Colo., reports this week that W. S. Stratton has sold his Independence mine to Englishmen for a sum based on an examination of the property last December, when it was estimated that the ore in sight was worth $6,000,000. Mr. Stratton is reported to have taken over $5,000,000 out of the Independence.

ROASTING always precedes chlorination. The barrel process originated with Mears and has been much improved by J. E. Rothwell. A full illustrated technical description of the barrel process appeared in the issue of Dec. 4th, '97. Under ordinary circumstances, barrel chlorination should cost about $3 per ton as a minimum.

IT has been figured that while in '70 one horse power in a 1000 H. P. steam plant cost $38.14 per year, on a consumption of 10 lbs. of steam per H. P. per hour, such a plant should now be run at a cost of $16.31 per year per H. P., though on that basis $20 per year is the accepted figure, in this regard much depending on the locality.

RECENT British Columbia legislation makes it illegal for miners to be employed underground more than eight hours in the twenty-four. This meets with great objection from miners and mine owners. Ainsworth miners have been getting $3 for a ten-hour day; under the new law the employers say they can pay but $2.40. Slocan miners who find their wages cut from $3.50 to $2.80 per day by the enforcement of the new law also object, and have petitioned for repeal.

THE Transmississippi Congress meets in Omaha, Neb., May 31st, '99. The Mining Congress meets in Milwaukee, Wis., in September. The American Institute Mining Engineers meets in San Francisco in October. The California State Miners' Association meets in San Francisco after the mining engineers have had their convention.

THE Denver & Rio Grande Railroad Co. preserves among its records a canceled check for $75,000 which it paid to the Colorado Coal & Iron Co. in '82 for 1000 tons of rail. To-day the price of steel rails at Chicago is $21 per ton, and the Colorado Fuel & Iron Co. is delivering about 15,000 tons per month, and meeting the demands of competition.

IN Belgian mines whenever men are being hoisted in a shaft a capable assistant must be near the engineer in charge of the hoist to replace him if from any reason the latter fails to promptly and properly attend to the work, and, like his principal, the assistant must give close attention to the signals, the indicator and the working of the engine.

A CALIFORNIA dam has been built of rough stone without mortar, founded on rock. Its height is 70 feet, base 50 feet, top 6 feet. The inside slope is secured by 3-inch plank secured to 12x12-inch timbers let into the stone work. The core of the dam—about one-fifth of the whole—consists of stone roughly thrown in; the balance of the stone work was carefully laid by hand.

NITRO POWDER which is frozen or too cold to "shoot" effectively may be safely thawed by placing it in a double vessel, as two tin cans one within the other, the outer can being filled with water, which should be heated gradually. This will thaw the powder slowly and safely. It is always extremely dangerous to thaw powder by placing in a stove oven, under a stove or near an open fire.

THE heaviest metal is osmium, specific gravity 22.5. Platinum's sp. g. is 21.5. The latter fuses at 3255° F. The ordinary composition of platinum ore in Russia is: Platinum, 78.90%; iridium, 5%; osmium, 1.9%; rhodium, .9%; palladium, .3%; copper, .7%; iron, 11%. In California it is found only in connection with placer gold. It is rarer than gold; its present price is about $17 per oz. to the consumer.

IF A by mistake does assessment work on B's claim, A supposing it was on his own claim, the loss is A's and the advantage B's. The law requires that the work shall be done, and does not require how or by whom. Still, under the circumstances B would be "a mighty mean man" if he didn't make it all right with A, if it was evident that it really was a mistake and that A did the work in good faith.

THE point of greatest economy in the transmission of the electric current is reached when the interest on the amount of money invested in the transmission wire is equal to the cost of generating the power lost in the transmission. It is not practicable to give absolute or unvarying figures as to the percentage of copper loss in current transmission, though it is ordinary to thus figure on a 10% loss in the transmission.

AT Carson, Nev., on the 27th ult., Judge Hawley rendered a decision in the case of Hanchett vs. Blair, denying petition for rehearing. Each claimed valuable mining property in Silver Peak, Esmeralda Co., Nev. The decision was in favor of Blair; judgment was entered in the case for $573,978.71. Local opinion greatly favored Hanchett, as he had ordered some machinery and was going to spend considerable money.

THE Western Federation of Miners now proposes to build and maintain a home for old and disabled miners. The idea is to secure a suitable site and levy an annual assessment on the members. Three sites have already been offered, one in Colorado, one in Utah and one in Nevada. The idea has been favorably discussed at various times. The California Legislature some years ago passed a law creating a State hospital for sick and indigent miners, but made no provision for the necessary funds.

SAMPLES of mica continue to be received from all parts of California, from Utah, Colorado, Oregon and Idaho. The best sent recently are from Bakersfield, Cal., and Cornucopia, Or. As heretofore stated, the value is in direct proportion to the size of the sheets, quality being equal. Scrap mica, or that produced in sheets less than 3 inches square, is not considered worth getting to market. White mica scrap is used for "silvering" wall paper, and scrap mica of any color is utilized for fire proofing, but the supply of "scrap" being usually 70% of the total product makes its price proportionate to its plenteousness.

THE flouring of quicksilver in an arrastra is unusual, and when it does occur may be due to any one of a number of causes. The pulp may be too thick, or grease may have gotten into the arrastra basin in some manner. Black oxide of manganese in ore has a tendency to cause "sickening," as also arsenic. Mercury which has become so finely divided from any cause that the particles refuse to reunite, may be collected by slowly adding sodium, which forms an amalgam. Cyanide of potassium may also be used with good effect in an arrastra, if no copper plates are used. Should black oxide of manganese be the cause of "flouring," quicklime added to the charge will have a beneficial effect.

AMONG the amusing notes of the week is one concerning "a carload of lead ore on the way from Maine to Denver, where there will be no smelting charges." That is from a Boston paper. San Diego chronicles the perfection of a process to extract gold from sea water, thus bringing up that old familiar fraud. The Boston prospectus of a California copper mine "on the same range as the United Verde of Arizona" where a smelter is "going" to be built, seems sufficiently alluring to the early Boston investor. California rains have produced the usual number of overlooked nuggets on forgotten dumps, and the annual Josephine county, Oregon, chicken has been heard from with gold in its gizzard, the amount this time being $1.25—a more than average yield. Olympia, Wash., is again to the fore with the perennial pine, which, when burned, disclosed gold in the ashes of the bark thereof, and the Colorado tin and Yuma white gold is also in evidence.

IN liquid air, as produced by C. E. Tripler of New York City, an india-rubber ball becomes as brittle as glass when immersed therein, and a piece of copper assumes the consistency of wax. Hard steel tubing breaks like an eggshell when placed in it, alcohol soon freezes to a solid mass and quicksilver, solidified, may be used as a hammer. The nitrogen of the liquid air boils off first, and there remains liquid oxygen of great purity. A diamond burns with brilliant scintillation in the liquid oxygen, while iron is rapidly consumed. Liquid air, on account of its contained liquid oxygen, is strongly magnetic and leaps up between the poles of an electro-magnet, assuming the general shape of an hour-glass. The latest developments in the manufacture of liquid air make it evident that all matter is subject to cohesive attraction and the state in which a body exists is dependent only upon temperature and pressure. It is proposed to use liquid air as a source of energy, and already the industrial world has set about the task of putting the new force into harness.

NEW trial has been refused in the case of the Matoa, Colorado, Co. against the Chicago-Cripple Creek Tunnel Co., and it is now thought that the case will go to the U. S. Supreme Court. The final decision of this cause celebre would settle some very interesting questions. First, whether a tunnel may be driven across a previously located claim. Second, whether a patent on a junior claim located across the line of a tunnel which was discovered and the discovery shaft sunk on the line of the tunnel, junior to the tunnel, and which was not adversed by the tunnel, the tunnel bore not having reached the claim, can claim all ore apexing within the boundary lines of junior claim. Third, whether a settlement made between a junior claim and a senior claim for a patent, and a senior claim, instead of adversing, takes a deed for the ground in conflict, whether such deed will relate back and give title to conflicting ground as of the date of the original location. The more recent suit brought in the United States District Court in Colorado by Cone & Robinson, owners of the Doctor mine at Cripple Creek, against the Roxana Gold Mining and Tunnel Co., in which plaintiff asks Judge Hallett to enjoin the Roxana Co. from running their tunnel through ground owned by the plaintiff, has practically been determined by the above decision.

LAST Saturday at Washington, D. C., the acting Secretary of the Interior rendered a decision of some importance to miners. The U. S. statutes require that notice of an application for patent for a mining claim shall be published for sixty days, and also that all adverse claims shall be filed during the sixty days of publication. Heretofore the mining regulations have provided that when notice is published in a weekly newspaper ten consecutive insertions are necessary. Under this rule the tenth insertion always occurs on the sixty-fourth day, which is after the expiration of the period required. In the decision rendered last Saturday the Secretary holds that the time fixed by the statutes for publication and for the filing of adverse claims is sixty days, and that the existing regulation undertakes to enlarge this period and is for that reason inconsistent with the statutes and of no effect. In effect it is said that the land department cannot by regulation change the statutes. The Secretary therefore approves the publication in this case, which included nine insertions in a weekly newspaper. In another case, on the same day, the Secretary holds that an adverse claim filed after the publication has been running for sixty days cannot be recognized, even though it was filed before the tenth insertion in a weekly newspaper. The two cases were Davidson vs. Elias G. M. Co., from the Pueblo district, Colorado, and Lizzie Elderson vs. United States, from the Salt Lake district, Utah.

ORDINARILY it is believed by many miners that where a candle will burn the air can with safety be breathed. That this is not always so has been repeatedly shown, and the lighted-candle test is not an absolutely safe one. At a recent inquest on the death of two Australian miners, who lost their lives from foul air in a shaft into which a lighted candle had remained burning, the fact was given such prominence that the Secretary of Mines took it up and secured expert opinion, with the result, as in similar investigations, of a statement to the effect that foul gases destructive to human life, yet permitting a candle to remain lighted, may exist in underground workings. An interesting paper, going into this whole subject in detail, was read at one of the recent meetings of the American Institute of Mining Engineers. The tests, though conclusive, were, however, too extended and elaborate to be of immediate practical value to those ordinarily desirous of knowing whether they might, with safety, enter a shaft or tunnel. Where is present 10% of carbon dioxide a living being will experience severe distress while a candle will burn dimly. In the case of "blackdamp" (87% nitrogen and 13% carbon-dioxide) the light of the candle goes out when 16% is present, while human life is not endangered unless a percentage of 28 is reached. Even 1% of carbon monoxide is fatal to life, but does not extinguish the candle flame. Hence it is manifest that the lighted candle test is not wholly a safe or sure one wherever enters in the element of danger.

SINCE Jan. 1st, '99, this paper has received the names of 371 new subscribers, which, for ninety days, is not bad, when it is considered that none but intelligent and progressive men are likely to subscribe for such a journal, which does not cater to the tastes of the many. Some time ago the leading authority on the subject in this country made the authoritative statements that appear on the opposite page of this issue. It is believed that since then the merits of this paper have been so further cordially recognized by increased subscriptions as to justify a still more favorable statement from the same source. The constant accession of new names to the lists of men who everywhere throughout this west half of America realize the weekly need of such a publication calls to mind that some time ago the statement was made in this column that the names of 179 new subscribers had been received in this office in one month. The accuracy of this statement was questioned, whereupon was published the name and address of each of the 179 new subscribers received in thirty consecutive days, with a request that any one who doubted the truth of the statement write any one of the 179. During the succeeding months several of the 179 wrote stating that the gratuitous publicity given their names had resulted in their receiving sundry free copies of "mining journals," and in the case of one of these "journals" it would seem as though the whole 179 were since in constant receipt of that publication. So that it has not since been deemed advisable to repeat the publication of such a list, the sole idea in the one instance mentioned being to afford exact and sufficient proof of the accuracy of the statement made regarding the receipt of the names of new subscribers.

The Genesis of Petroleum and Asphaltum in California.

NUMBER IX.

Written for the MINING AND SCIENTIFIC PRESS by A. S. COOPER.

Veins of asphaltum, being rents, seams and fissures filled with asphaltum, occur usually vertical or not far from vertical. An innumerable number of small faults, contortions and breaks occur in the formation in which these veins of asphaltum exist. These veins of asphaltum occur in the vicinity of red shales or shales that have been burned and contracted by chemical heat; the contraction of the shales opened and open cracks and seams in the adjoining formation permitted the ascent of the asphaltum. These cracks and seams extend to such depths as to reach deposits of petroleum oil.

From observations made at Asphalto, Mount Solomon, La Patera and other places, it would appear that these fissures and rents and faults are filled with bitumen in the following manner: Heavy petroleum oil at various depths below the surface of the earth in porous or seamed strata is urged upwards principally by rock pressure. The subsidence of the formation in which the asphalt veins occur is caused by the contraction of the shales by heat. In consequence of the subsidence the shales and sandstones are very much broken and contorted. Around the edges of these subsidences these veins of asphaltum are found.

The specific gravity of the asphaltum is too great for it to be buoyed up by water and the formation in which the veins exist is too broken for gas to exert a pressure, but hydrostatic and gas pressure do in some instances urge the bitumen upwards. When ascending in porous or seamed strata the petroleum oil is partly evaporated, the evaporated portion forming gas, which reaches the surface through passages which are closed to the viscous oil. The oil is readily oxidized on account of its divided state, and if sulphuretted hydrogen or sulphur dioxide is present the oil is resinified, forming asphaltum. By sulphuration, oxidation and evaporation the petroleum oil is finally hardened. When nearing the surface it is indurated to such an extent that it rarely ever shows itself. Polymerization of the bitumen by the photochemical action of the light also assists in the induration of the bitumen when nearing the surface.

Adjoining the selvage of the veins when near the surface of the earth the asphaltum is brown and friable, fully two-thirds of which is asphaltene. In the interior of the vein it is black and shining and when cold breaking with a conchoidal fracture, fully two-thirds of which is petrolene. The proportional amount of petrolene and asphaltene existing in the asphaltum is very variable. When at a sufficient depth so as to be removed to a considerable degree from atmospheric influences the brown margin of asphaltum does not exist. As a general rule, the farther from the atmospheric influences the more liquid the asphaltum will be. Bivalvular shells filled with petroleum are frequently found in these asphalt veins, the bitumen on the shells being much more liquid than the surrounding asphalt and of a lighter color. The asphalt veins are rudely parallel to the periphery of the red shale deposits and exist along the margin of the subsidences, the seams for the reception of the asphalt having been opened by the movement of the formation towards the contracting shales, permitting the ascent of the asphalt forced up by rock pressure. The parallelism of the veins to the periphery of the burnt shales is frequently changed by the varying hardness of different strata or by orogenic contortions.

When the hanging wall consists of hard and close-grained strata the bitumen will accumulate below the same, which on account of its being conformable with the plane of bedding of the adjoining strata give it the appearance of having been deposited at the same time as the other strata. When these shales are burning large amounts of sulphur vapors are disengaged. It is reasonable to believe that these vapors sulphurized the bitumen in their neighhood, forming asphaltum. Mineral waters containing sulphuretted hydrogen in large quantities usually accompany the ascent of the asphaltum. The earth adjoining the veins is usually charged with mineral matter deposited from infiltrated mineral water. If these openings and sulphur vapors had not been made and generated through the contraction and burning of the shales by chemical heat the asphaltum would not have been formed, nor could it have reached the surface of the earth.

The physical characteristics of the asphaltum filling these veins are extremely variable. In consistency it gradates from a hard rock to a viscous condition. The asphaltum contains intimately mixed from 1% to 70% of impurities. The impurities hardly ever exceed 75%. The presence of more than 75% of impurities makes the bitumen so stiff that it cannot be forced through the cracks and seams. In the vicinity of the injected veins there are beds of shales containing from 10% to 15% of bitumen, but existing rock pressure is unable to move them.

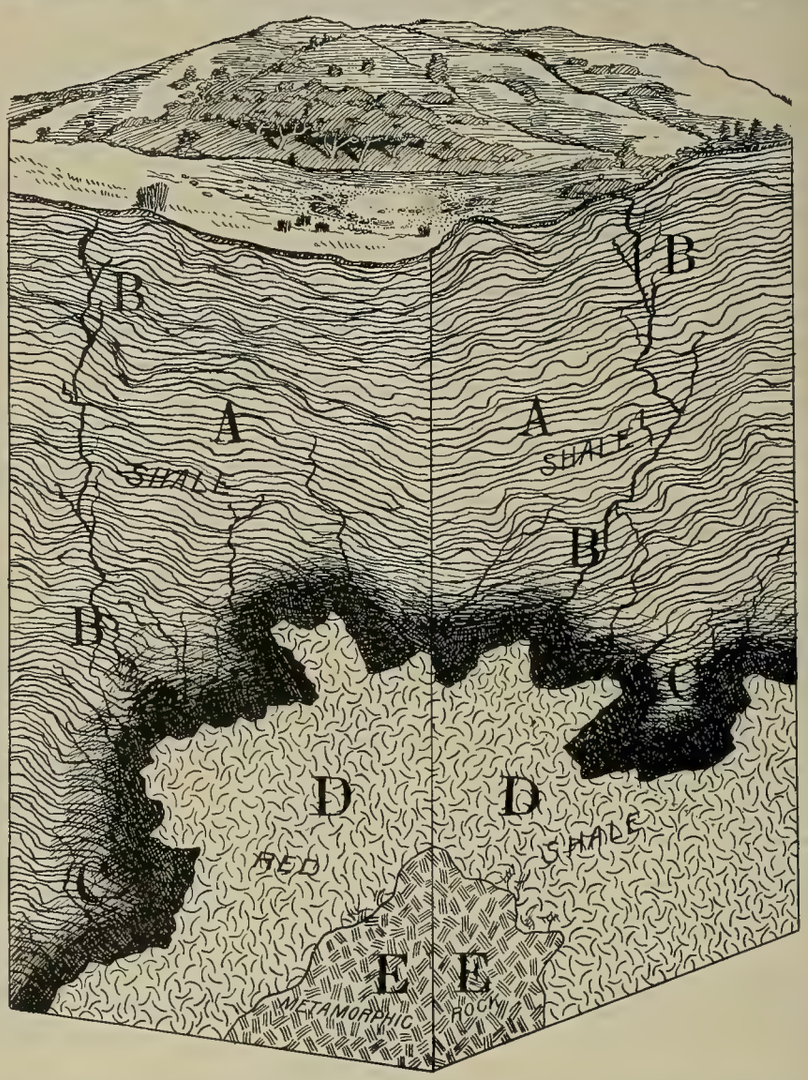
The impurity in some of these asphalts is infusorial earth, in others sand, while in others finely ground shales and angular fragments of shales and fossil shells or all of these impurities may be present in the same deposit. Shale preponderates as an impurity, in fact the impurities are derived from the rock which the asphaltum encountered during its ascent. Most of the time the impurities are very fine and light, making the refining of the asphalt by any known process difficult.

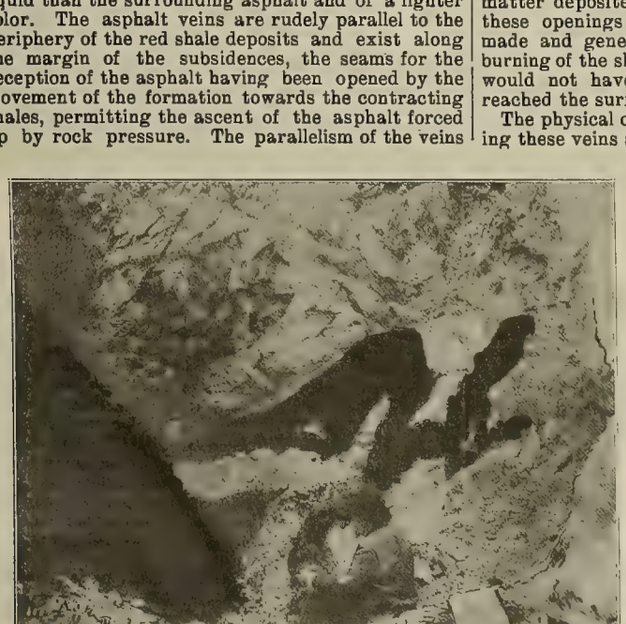
The thickness of these veins of asphaltum are variable; sometimes they are 20 feet in thickness, decreasing until they become the thickness of a knife blade. In exploring for asphalts these small seams are followed and often lead to thicker parts. The asphaltum breaks with a conchoidal fracture, some of these conchiform pieces being 10 feet in diameter. The viscous asphaltum cannot enter the interstices or pores of the rocks of the formation; especially is this true where the pores or interstices of the rocks are filled with quarry water, consequently when it is urged upward and forward by rock hydrostatic or gas pressure it exerts a pressure in all directions (similar in action to a hydraulic press) and through this pressure pushes the rocks asunder, making room for itself.

The pressure required is not great when the shale is contracted on one or both sides, the asphaltum being constantly alert to take advantage of any movement of the earth. Next to these bituminous veins the formation is of a bluish color, owing to the presence of a slight amount of bitumen. These veins entered the formation subsequent to its subsidence, as the veins are not faulted; although frequently very tortuous they are continuous. These veins sometimes bisect the brown bituminized sand, showing that they were injected subsequently to the filling of these sands with bitumen and even after they had become brown and indurated through long exposure. These veins of asphaltum frequently contain fossil shells and shark's teeth which must have been brought up from lower strata, as no similar fossils occur in the adjoining walls of the vein. These fossil shells are filled with bitumen mixed with the silt and sand that entered them when they died.

The bitumen in the shells must have been much more liquid when it entered them than at the present time. At the present them the bitumen is too stiff to enter the shells. Sometimes the bitumen in the shells is much softer than that in the veins and sometimes it is of a yellow color. Slickensides on both sides of these bituminous veins show that the material has moved upwards. Fossil shells imbedded in the hanging wall of these veins have plowed grooves in the asphaltum as it ascended. At the Waldorf mine a groove was formed in this manner 10 feet in length.

These veins of asphaltum in several instances are found injected into the detritus which has descended from the adjoining hills. Tunnels and shafts excavated in the formation containing these veins have been partly filled with the ascending bitumen. At the La Patera mine, in sinking upon some asphaltum, it was discovered that the excavation was being made in an old shaft, which, outside of the earth that had fallen into it, was filled with asphaltum. At a depth of 15 feet an old-fashioned pick and sledge hammer were found, which must have been buried for a long number of years. Enquiries were made, but it could not be ascertained who sunk the shaft.





ASPHALT MINE, SANTA MARIA, CAL., ASPHALT CO.

At the La Patera limpid sea water is inclosed in cavities in the asphaltum, its limpidity showing that sea water has no effect upon it. In the Santa Barbara channel, below high-water mark, near the La Patera mine, veins of this mineral occur. Owing to the plastic nature of this character of asphalt and the broken condition of the formation in which it usually occurs, it is very difficult to mine. When inclines, tunnels, shafts and other excavations are made in asphalt, or near it, they are hard to maintain, as the asphaltum lying above or near the excavations, even below them, commence to move through rock pressure, so that the excavations are soon destroyed.

Deposits near excavations give evidence of their existence by the earth bulging into the excavation. Wedges, picks ond other tools used in mining the asphaltum become sharp, instead of dulling.

When mined and relieved from pressure, occluded gas expands in the asphaltum, making it very vesicular.

In the map on the opposite page, *A A* portrays unaltered shale, greatly distorted by subsidence caused by the contraction of the red shale, *D D*. *B B B B*, veins of asphaltum squeezed and forced up by rock pressure exerted by the shale *A A*, owing to their broken and contorted condition.

C C, shales filled with condensed hydrocarbons, which were vaporized by hydrothermal heat in the red shales.

Near or adjoining the red shales the shales are filled with liquid asphaltum; in some places the shale and the liquid asphaltum have formed a mud, which is forced outwards and upwards by the weight of the superincumbent shale through cracks and seams to the surface of the earth. Further away from the periphery of the red shale the shale has a smoky appearance, owing to the condensation of different vapors generated by hydrothermal heat in the red shales, *D D*. *D D*, red shales which have contracted through the action of hydrothermal heat, such contraction causing subsidences in the overlying shales, *A A*—such subsidences opening fissures and cracks, *B B B B*, permitting the ascent of the bituminous mud urged upwards by rock pressure and, maybe, gas and hydrostatic pressure. Underlying the red shales is serpentine, being shales metamorphosed to a greater extent than the red shales. The half-tone engraving on the opposite page gives a view of a formation into which veins of asphaltum have been injected.

(*To be Continued.*)

A New Method for the Determination of Zinc.*

By A. C. LANGMUIR.

Practically two methods only are in general use for the gravimetric determination of zinc. Of these, the carbonate method, with its many imperfections, is being displaced by the phosphated method, at least in America.

With care the latter will yield excellent results. In our practice it is customary to use ammonium phosphate in place of the usual sodium salt, and after the precipitation of the phosphate to destroy the slight excess of ammonia remaining after heating on the water-bath, by the cautious addition of dilute acetic acid. Under these conditions the filtrate is free from zinc.

Directly igniting the sulphide and filter, and weighing as oxide or sulphide, has been used, but is open to serious objection if the amount of zinc is at all large.

As far as we are aware no one has proposed the solution of the sulphide in nitric acid, the evaporation of the solution so obtained and the conversion of the residue to oxide by ignition. As a second precipitation and washing is avoided it is quicker than the carbonate or phosphate methods, and is preferable to the latter in that the impurities almost invariably present in the zinc precipitate may be easily determined and allowed for.

The sample of ore for analysis (one-half to one gramme according to its zinc content) is dissolved and the metals precipitated by hydrogen sulphide separated by the usual methods. After expelling hydrogen sulphide, the solution is colored by bromine water, and the iron and any manganese present are separated by ammonia. The precipitate is dissolved in hydrochloric acid, and the precipitation is repeated a second or third time if necessary.

If the ore is one which is known to be free from lime and magnesia the combined filtrates may be boiled down immediately with the addition of an excess of nitric acid to destroy chlorides and ammonium salts. After the removal of the chlorine, the solution is transferred to a weighed platinum dish, evaporated to dryness, ignited and weighed as oxide.

The troublesome filtration and washing of the zinc sulphide should be avoided if possible. In our opinion better results are obtained by the ferrocyanide titration of the solution of the unwashed sulphide than by any gravimetric method involving the filtration and washing of this precipitate.

The zinc is best precipitated as follows: Acidulate the warm ammoniacal filtrate from the iron with hydrochloric acid, add a few drops of sulphurous acid to neutralize the bromine set free, then three or four drops of methyl orange. Neutralize with ammonia carefully, and add ammonium sulphide drop by drop with constant stirring until a drop of the solution gives a dark coloration with a drop of dilute ferric chloride solution on a porcelain plate, showing a slight excess only of ammonium sulphide. The liquid is now warmed on the water-bath until the sulphide has settled, and is filtered through a double ribbed filter. Under these conditions a clear filtrate is invariably obtained, but if washing is attempted the filtrate is frequently cloudy.

We therefore dissolve directly, without washing, in hot nitric acid (1:3) or in dilute hydrochloric acid if cobalt or nickel are present, and correct the weight of the oxide subsequently found for the small amounts of lime or magnesia present. It is well to make a qualitative test for these elements in the filtrate from the sulphide. If absent or in small amount the correction in the weight of the oxide may be omitted.

The solution is boiled down rapidly in a casserole with the addition of nitric acid to expel chlorides. When almost dry the contents are rinsed into a weighed platinum dish or crucible. The evaporation is continued on the water-bath or hot-plate until dry, when the nitrate is ignited at the full heat of the Bunsen burner. As some zinc sulphate, which is always present, is not decomposed at this temperature, it is necessary to break up this compound by intense ignition over the blast-lamp. Any lumps should be first broken up by a blunt glass rod. Ammonium carbonate may be used but is liable to occasion some loss.

It may be possible, by igniting at a low heat, to weigh the zinc as sulphate, after evaporating with sulphuric acid. We are working on this now.

After weighing, the oxide is dissolved in hydrochloric acid and the small amount of iron always present thrown down with ammonia, ignited, brushed into the tared watch-glass in the balance and weighed directly. The filtrate is acidulated with hydrochloric acid, heated to boiling, and tested for sulphates with barium chloride. A slight precipitate will usually form, but this may, in general, be neglected if the ignition has been properly performed. If in weighable amount it may be treated as in the case of the iron, calculated to sulphur trioxide, and together with the ferric oxide deducted from the weight of the impure oxide.

If lime or magnesia were present the filtrate from the iron should be divided into equal parts, one of which is tested for sulphates and the other for lime and magnesia by throwing out the zinc as sulphide, and testing the filtrate by the ordinary methods. As a rule this is unnecessary unless the lime or magnesia is present in large amounts, for the sulphide is precipitated in dilute solution and the amount of lime remaining in the unwashed sulphide would usually be very small.

The correction for impurities may seem tedious but in reality it is quickly carried out. Richards has found that zinc oxide obtained by the ignition of the nitrate contains a little occluded nitrogen. This would only amount to a few tenths of a milligramme and may be neglected unless unusually accurate work is called for.

For the determination of zinc in alloys containing copper, tin, lead, iron and zinc, dissolve in nitric acid, evaporate to dryness, and take up with nitric acid if tin be present. Filter and separate copper and lead simultaneously by electrolysis. The solution should contain 5 cc. to 10 cc. concentrated nitric acid in 150 cc. to 200 cc. water. After removing and washing the electrodes carrying copper and lead the solution is evaporated to dryness in a weighed platinum dish and the residue ignited and weighed. Dissolve in hydrochloric acid and separate the usually small amount of iron present by ammonia. Ignite, weigh, and deduct from the weight of the zinc oxide. If nickel be present the weight of the combined oxides may be taken and the nickel afterwards determined, when the zinc may be found by difference.

Zinc in pure spelters is best determined by difference. In impure samples it is sometimes more convenient and equally accurate to determine zinc directly. Dissolve one-half gramme in nitric acid and separate the lead electrolytically in a solution carrying 10% nitric acid. Use the platinum cylinder in this case to collect the lead peroxide. Evaporate the solution to dryness in a weighed dish, ignite, and weigh. Dissolve in a little hydrochloric acid, reduce with two or three grammes granulated zinc, add sulphuric acid to complete the reaction, dilute with ice water to one litre, and titrate with permanganate. Correct for the amount of iron found. If cadmium, arsenic, or other impurities were present in more than traces the above method would be inapplicable unless modified to include treatment by hydrogen sulphide.

We have not found time to make an extended series of tests of this method, but, in numerous analyses of ores and the complete analysis of alloys in which in duplicate analyses the zinc was determined by the well-known methods, the author has convinced himself of the accuracy of the method.

*American Chemical Society.

Experiences of a Working Miner.

NUMBER VIII.

Written for the MINING AND SCIENTIFIC PRESS.

The R—— Company had a most unfortunate experience for some time after starting in business. The purchase price of the mine was so ridiculously small that I will not mention it, but it was only a drop in the bucket. The first investment called for more and for two or three years it was all outlay and no income. At last the mill was completed and the return of the tide was looked for, but it did not return—at least not at once. The mill man had some ideas of his own, and put them into practice. The mill was supplied with stamps, pans and settlers, the ore being worked by the Washoe process. This first mill man used so much water in the pans that the quicksilver would not mix with the pulp, and as a result very little amalgam resulted. Finally a new man was engaged. He was told of the extreme ideas of his predecessor and evidently determined to pursue a different course. He used so little water that the quicksilver floured and nothing could re-collect it, and it floated out of the mill and down the canyon, until restraining dams were built and the tailings saved. Mr. A——, who had been about the mill all this time — covering a period of several months—concluded that there might exist a medium between these two extremes, and made a proposition to the company to work for a percentage of the net proceeds. His offer was accepted, probably because prior to that such a thing as net results were an unknown quantity to them. A—— started in and the first ten days sent away $8000 in bullion, which was more than had been produced in two years. That year he shipped over $600,000 to the home office and made a fortune for himself. This experience is given to show that rigid adherence to any set plan or method is not productive of the best results unless, indeed, the best results have already been attained and then it is probably well enough to let it go at that.

Hearing of the rich mines at L—— I went there to have a look at them and, if possible, get a job. The place was described to me as a mountain of silver. Arrived at L—— I found a company actively engaged in driving a tunnel in mica schist, and pretty hard ground, too. The snow was about 2 feet deep, so I didn't have much of a chance to see the geology of the place except underground, which was not satisfactory. After a few days most of the snow had disappeared and my opportunity had come. On inspection of the "mountain of silver" I found a sheet of quartzite dipping about 15° and lying upon the upturned edges of an older formation. The silver was there but it was all in the flat sheet of quartzite and did not extend down into the schists. A shaft had been sunk through the quartzite and the tunnel was being run to connect with the shaft, at the bottom of which crosscuts radiated in three directions and the tunnel connection would make the fourth. This concern failed. The superintendent was an unapproachable, conceited individual, who knew nothing, but thought he "knew it all." I kept my own counsel, and the mine lies idle yet.

A few days ago I saw in the papers the statement that a California miner had attempted to thaw nitro powder by placing it under the stove in his cabin. It recalled to my mind an incident in my own experience. It was at Leadville, and the weather was cold. There was a good-sized cook stove in the office of the hotel (boarding-house) and a number of miners and others were sitting and standing about it. A man opened the door and asked: "Jerry, is that powder thawed out?" Jerry responded he did not know, and opened the oven door of the stove. Inside was a dinner-bucket with a dozen sticks of powder in it. I could not say whether the powder had thawed or not —didn't wait to see. It did not explode in this instance, providentially.

It is not only the managers of mines who make mistakes, but miners and prospectors owning claims who "get off wrong" often. When R—— was a booming camp, the C—— mine was looked upon as one of the best prospects in the country. About $1500 worth of work had been done on it and it did look fairly well. Then a new cut and shaft were started and they struck it rich. The gold could be seen in the rock 15 feet away. The boys were millionaires at once. The representatives of monied men were on the ground shortly after. The first offered $60,000 cash—that is to say, he would go and get his money and be back within four days. No agreement was signed, but it was understood that it was "a go." This individual had scarcely left camp when No. 2 came along, and, after a brief inspection of the mine workings and a longer inspection of the bunch of rich rock, offered $200,000, payable in two weeks. He only wanted to go to San Francisco to get the money. Fearing he might back out, the owners of the claim put this latter proposition in writing. Four days later No. 1 returned with a well-filled valise; but the boys could do no business with him. They told him if he would raise the price they would throw the other fellow off. He would not raise, but left in disgust, and, sad to say, the other

man never came back. The boys did a little more work, dug out their pocket, realized about $1600 on it, and then the property remained idle for a long time and was finally jumped by outsiders. Another similar instance I remember, where four partners were offered $90,000 for a prospect, but they insisted on $100,000. The capitalist was firm, however, and no transfer was made. Four years later, after a great deal of development, the claims were sold for $14,000. These are what I call serious mistakes for practical miners to make, and there are many such. Still they will smile grimly at the mistakes made by their superintendents.

I knew an aged prospector who owned several claims. The ore was not free, and he could not afford to have his ore assayed. The superintendent of a mine near by had a little talk with him one day and purchased one of his claims for $250. The old man was overjoyed. He went to the town a few miles away and bought a good large bill of provisions and mine supplies, determined to do more work on his remaining claims. When he returned, three days later, he was surprised to see that a road had already been graded up to the dump of the claim he had lately sold and a long mule train was loading up the ore. He had sense enough to know that the man who had bought the claim was shipping high-grade ore. To him a "wink was as good as a nod," and inside of ten days he, too, was shipping high-grade ore at a profit, and a little later sold out all his holdings and returned to a comfortable home. There are few who think he made a mistake in selling what appeared to be his best claim for a song. MINER.

Dredge Mining in California.

Written for the MINING AND SCIENTIFIC PRESS.

Dredge mining is undoubtedly likely in the near future to take a place as one of the important industries of the State of California.

Vast areas of placer ground were mined in the early '50's "to the water line," and as far below the water line as China pumps and current wheels rendered feasible. It is known that good values lay in the substrata which primitive methods could not reach; and many efforts have been made to evolve a machine that should render them available. The history of these machines so far, until quite recently, has been a chronicle of failures and disappointments; but it looks now as though the problem was in process of solution.

Between Biggs and Oroville there are now three large dredging machines working regularly in the Feather river, and two others are about finished and are expected to be at work within a few days. There are, so far, two distinct types of dredge working; three of them are endless-chain and bucket machines and two are of the shovel type, virtually large steam shovels, set on hulls, and fitted with gold washing apparatus.

The process of both types is practically the same. The gravel is lifted into a hopper, from which it is fed into a revolving screen or "grizzly," which separates the cobbles from the gold-bearing sands. The cobbles are carried by endless chain and buckets, or by a belt conveyor, aft the dredge hull, and stacked up so as not to interfere with the floatage of the dredge.

The fine sands, screened from the dredged mass are variously treated. Generally they are passed over tables covered with cocoa matting, which proves an excellent medium for abstracting the gold from the sand; running from these into sluices having the ordinary form of riffle, and from these dumped overboard at the stern of the boat.

The gold is of a flaky character, the pieces in size resembling bran. The gravel through the neighborhood where the dredges are working is about 30 feet deep and contains gold to the extent of about 20 cents a cubic yard. The dredges working at present are handling about 500 yards each per day of twenty-four hours, and the owners hope to gradually attain the best results as the work becomes more familiar. One owner says that, figuring the standing charges of interest and depreciation at fair rates, his daily expense was over $100, so that 500 yards per day at 20 cents per cubic yard was just about paying expenses, and more gravel must be got through the machines to afford a profit. When asked if some of the stories in circulation that the dredges were cleaning up $200 or $300 a day were correct, he replied that he believed that his dredge had handled more gravel in the month of February than any other dredge in the river and that his balance sheet for the month showed a net loss of $218.94.

However, at so early a stage in the game the machines are doing well to be paying expenses; and in the hands of the class of men who are operating them they are certain to gradually evolve a practicable and reliable machine.

Enquiries have been heard of damage being done the navigable rivers by the work of the dredges. Those working in the river are merely raising gravel from the river at one end of the boat and redepositing it at the other. At the ordinary stage of the river the water is not discolored a greater distance than a few feet from the boat by the operation, as the material is too heavy to remain in suspension in the water; and at high water stages, when the current might take hold of the newly moved material, the dredges are unable to work on account of the strong current. The dredges intended to operate in the lands adjoining the river are launched in excavations previously dug for them. In digging out of the river bank they only deposit new material in the river for the few days they are cutting through the river bank to the lands adjoining.

San Francisco, March 27th, '99.

Saving Fine Gold in Sluices.

TO THE EDITOR:—For some time I have been experimenting with various methods of saving fine gold in sluices, and thinking the result of my experiments may interest and possibly benefit others, I offer it through the medium of the MINING AND SCIENTIFIC PRESS:

I have discarded all riffles and have substituted grain sacks in the bottom of my sluice boxes. They are secured in place by the use of tacks at the upper end of each sack, the sacks having been cut to fit the boxes. I lay a sack at the lower end of the box first, allowing the next above to overlap it 5 or 6 inches, and so on to the upper end. I then tack a thin strip of wood along each side of the box on top of the sack to hold them in place. I have found a single 12-foot box sufficient, but below this first box I have arranged an undercurrent, set at a right angle, and this is also laid with sacks, as a precautionary measure. I rarely find anything in it, however, unless I run six or eight days without cleaning up, and then I find a little, so it shows it is just as well to have it, but it does not pay to clean up frequently. I have found that by this means all of the fine gold may be saved, provided I give the boxes the proper grade. In my experience I have found 5 or 6 inches fall to a 12-foot box gives the best results, with a stream of water about 1 inch deep running in the box. I do not shovel in the large boulders, but cobbles the size of a man's fist go through all right. In cleaning up I take up the sack at the upper end first, handling it carefully, and wash it by dipping and shaking in a tub of clean water. I wring it out and lay it aside, treating each piece in like manner. In laying these sacks in the box, I use only one thickness. When the several pieces of sack have been removed, I sweep the sluice box down toward and into the undercurrent, admitting only enough water at the head of the sluice box to accomplish this. The undercurrent is cleaned in similar manner. All the sweepings are put in the tub with that from the sacks, and the whole carefully panned with quicksilver, not taking too large a quantity of sweepings at a time. When all has been amalgamated, I squeeze out the excess quicksilver and retort. Where there is coarse gold in the gravel I put a few riffles across the lower end of my lowest sluice box. My boxes are 16 inches wide and 10 inches deep. The undercurrent is made by cutting a slot ⅝-inch wide across the entire width of the upper box near its lower end. I find considerable "rusty" gold in the black sand and suggest that miners treat their black sand with nitric acid, which removes the coating of iron oxide and permits the gold to amalgamate. J. W. MOORE.

Bragdon, Cal., March 22d, '99.

The suggestions made above will doubtless prove valuable to those having fine gold in their placers, which is saved with difficulty. It is evident, however, that sluice boxes set on a 5 or 6-inch grade and using a sluice head of water only 1 inch deep will not permit the handling of a very large quantity of gravel. It would probably be found to operate very satisfactorily as an auxiliary to regular sluicing methods which employ a heavier fall and a full sluice head of water, and setting an undercurrent as suggested, in the same manner, with two lengths of box instead of one, or with the second undercurrent if it seemed necessary, providing the boxes above with riffles as usual, and making his upper box with sacks, etc., the undercurrent. Others having had experience in saving the fine gold found in placers are invited to contribute any information they may have on the subject.

Results to Advertisers.

The following unsolicited testimonial is received. These indorsements of this paper as a trade producer are never asked for by the paper nor any of its representatives, but are often received and always cordially appreciated:

Publisher Mining and Scientific Press: Permit me to compliment you upon the returns received by us from a small "ad" recently inserted in your columns. We received over one hundred responses to same, covering every State west of the Rocky mountains, about ten Eastern States, including New York and Massachusetts, and from Mexico, Australia and the Hawaiian Islands.

The Crosshead and Trip Rope.

TO THE EDITOR:—I would like to know about the latest improved plan of crosshead over shaft bucket, also the best plan for dumping the bucket at surface into car—shaft to be 4½x5.
Rossland, B. C. W. S. H.

An answer to the above, in so far as it relates to the crosshead, will be found on page 350, this issue. A very convenient method of dumping a bucket so that its contents will fall into a car is by means of a trip rope, the upper end being secured to the gallows frame, or, in case of a two-post frame, to a frame projecting from the gallows itself. The shaft should be carried up above its collar by 6x6-inch timbers and enclosed on all sides except the back, which should remain open to the collar for the purpose of landing the bucket with tools, etc., and for sending down timbers and for other purposes. This curb-like structure should be higher at the back than in front and should be provided with an inclined door, which extends over the shaft, thus protecting miners working below. The door may be made of 2 inch plank and covered with an iron plate, the weight being equalized by a counterweight. It should be securely hinged at its lower end, and a lip should project far enough forward to deliver ore or waste into the car standing on the track in front of the shaft. When the bucket is to be hoisted, the top man goes to the shaft; and when the bucket has cleared the door, the door is lowered into place, the hook of the trip rope caught in the ring beneath the bucket and the bucket lowered by the engineer. It tips forward, the top man keeping it from swinging sideways, and its contents are discharged into the car and on the iron plate of the door, from which it slides into the car. Where it is desirable to wash dirty ore for rough sorting, a platform should be built about the collar of the shaft high enough for a car to pass under it. The ore is dumped on the floor of the platform by means of a trip rope, as above described, but at a greater distance from the shaft, by having the trip rope secured to an arm projecting from the gallows-frame. Having washed the ore, and thrown either the ore or the waste into a separate pile, the balance may be quickly shoveled through a trap in the platform into the car beneath. The shaft should be covered by trap doors for the safety of men in this case also, but the ore need not be dumped on the door, as in the former case.

Loss of Gold.

Cyanide managers will be interested in the results obtained from tests of the material taken from the chimney and flue of the Boatman's cyanide plant at Reefton, N. Z. The tests were directed to the examination of the furnace chimney as to the loss of gold in smelting. A sample of the incrustation was composed for the most part of brick, owing to the strong adherence of the coating of zinc oxide, which was not readily detached: The incrustation under the microscope presented the appearance of a yellowish white efflorescence, but showed no metallic gold. The sample taken weighed 20 lbs. This was crushed roughly and separated into two portions on a 30-mesh screen: Pass 30-mesh screen, 13 lbs.; refuse 30-mesh screen, 7 lbs. The two samples were then assayed separately as follows: Fine sample, 8.416 grs. pure gold per lb.; coarse sample, 3.263 grs., which shows the 20-lb. sample to contain 5 dwts. 12¼ grs. gold. By carefully panning the finely crusted material a yellow film or tail was seen, having the appearance of a stain or coloring. The microscope showed this to be finely divided particles of metallic gold, rich in color, of spherical form and of very even size. In this furnace only a little over £1000 worth of bullion was smelted, and as only a small portion of the fume would deposit itself upon the walls of the chimney the loss may have been very considerable. Whether the gold was carried away by the draught as fine slimes or by volatilization of the bullion there is nothing to show. The furnace used to draw well and had a stack of about 15 feet. In smelting, where the slimes are well oxidized and properly fluxed the loss of zinc must be extremely small, as nearly all the zinc goes into the slag, excepting that portion reduced in the smelting, which partly enters the bullion and partly escapes escapes as fume. It is evident, however, that the portion which does volatilize, and also the fine particles carried away by the draught, must be rich in gold and worth saving. The experiments thus recorded call for extension in other localities.—South African Mining Journal.

A Correction.

TO THE EDITOR:—In "That First California Mining Electric Plant," in issue of March 25th, the word "removed" should be "rewound." All moving and removing was done by our own employes, while rewinding of armatures was done at San Francisco by the California Electrical Works and Prof. Keith.

Oakland, Cal. A. K. BEATSON.

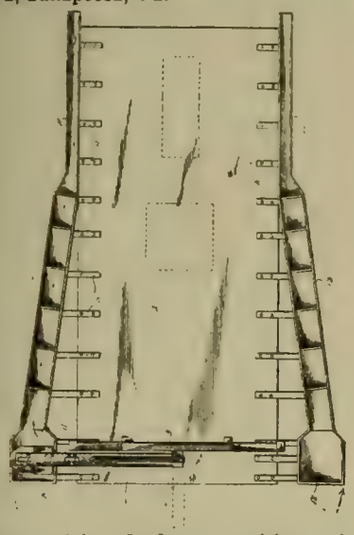
FIFTY casks of peculiar construction are to be set adrift in the Arctic ocean the coming summer by whaling vessels going through Bering straits, to determine if possible the currents of the Arctic and the theory of an open passage around the pole.

Latest Mining and Metallurgical Patents.

Patents Issued March 21, 1899.

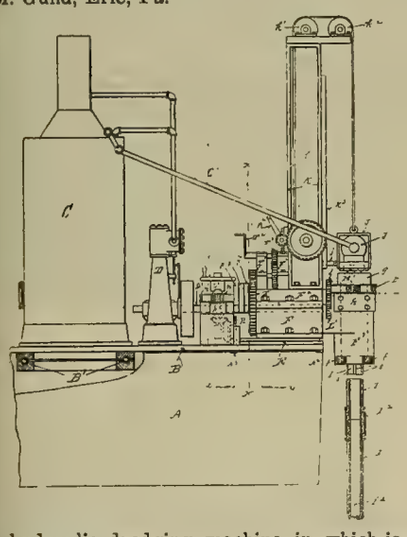
Specially Prepared for the MINING AND SCIENTIFIC PRESS.

PLACER MINING DREDGE.—No. 621,377; G. W. Shepard, Tallapoosa, Ga.



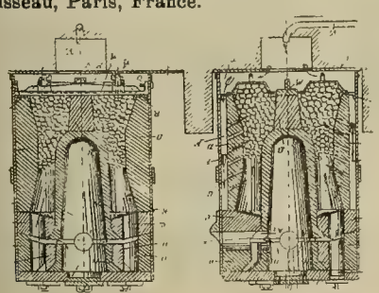
A placer mining dredge comprising a barge or scow, hoppers supported at one end of the barge exterior to side line and gunwales and at opposite sides at points equidistant from longitudinal axis; sluices communicating with the hopper on opposite sides and outside the barge above the plane of the deck, inclined downward from the hoppers and inwardly into close relation with the barge tailings sluices at opposite sides, a swinging crane near the hoppers, an excavator bucket carried by the crane, and means for swinging the crane in opposite directions to discharge the contents of the buckets into the oppositely-placed hoppers alternately.

HYDRAULIC DREDGING MACHINE.—No. 621,408; H. M. Guild, Erie, Pa.



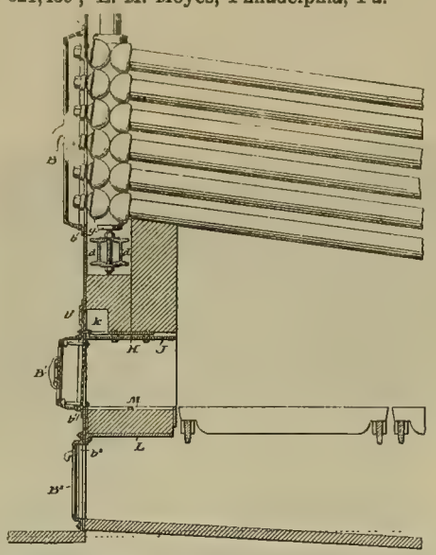
A hydraulic dredging machine in which is combined a bed plate pivoted at one end on the deck of a boat, tracks on which the free end of bed plate travel back and forth, an engine and boiler mounted on bed plate, rack and gear mechanism for moving the free end of the bed plate back and forth, a turntable mounted on the outer end of the bed plate, a hollow trunnion mounted on turntable, sleeve mechanism mounted on the outer end of trunnion and adapted to be rotated, a vertically moving tube supported in and rotated by sleeve mechanism, a pump mechanism communicating with the upper end of tube, worm and spur gear mechanism for rotating the sleeve and tube therein, and ribs on the periphery of the tube.

FURNACE FOR SMELTING METALS.—No. 621,715; L. Rousseau, Paris, France.



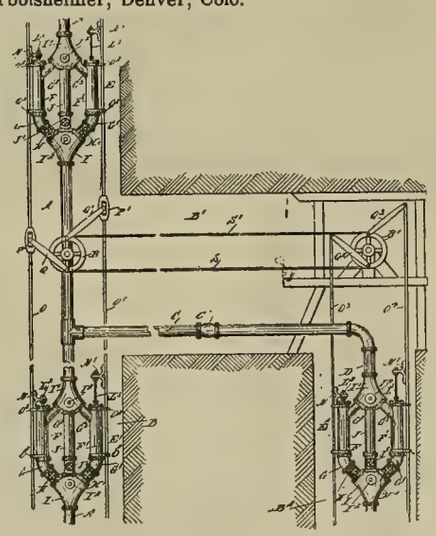
In a smelting furnace, the combination with a hearth, of suitable means for supplying fuel from above, a crucible pot arranged and suitably mounted in the hearth, a casing surrounding and adapted to carry the hearth or combustion chamber, a fire bridge or crown supporting the crucible at its upper end, channels connecting the hearth and crucible pot; means associated with the crucible pot for the escape of gases of combustion and suitable means for its oscillation, a pit contiguous to and below the combustion chamber, vertical flues formed between the casing and the wall of the combustion chamber and communicating with the pit, the wall being provided with downwardly inclined channels adapted to admit air to the combustion chamber, whereby an intimate mixture occurs and the combustion of gases is completed and suitable means for supplying air under forced draft to the pit.

FURNACE CONSTRUCTION FOR STEAM BOILERS.—No. 621,459; L. M. Moyes, Philadelphia, Pa.



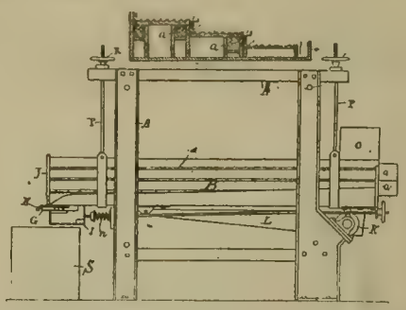
In a boiler furnace, a dead plate formed of a course of brickwork or fireclay cement covered by an iron grating, a combination of the coupled I beams *d*, bolts *e*, passing between coupled I beams, and a swinging support for the upper end of bolts, a series of seats *g*, supported between I beams whereby the alternate short manifolds of the forward end of the boiler tubes are supported; the combination of two upright beams at the front corners; a cross plate mounted between upright beams upon which the arch of the firing door is supported; a second plate a short distance below the supporting plate supported thereby, and which forms the top wall of the firing door; an air space between the two; an air chamber formed in the brickwork of the arch immediately in front of air space, and a register through which that chamber opens in front of the furnace.

DEEP MINE OR RELAY PUMP.—No. 621,667; Geo. Herbolsheimer, Denver, Colo.



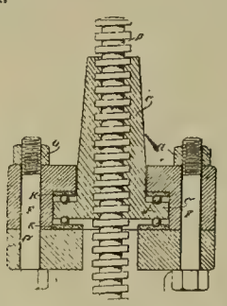
A deep-mine relay pump comprising a series of pumps arranged in successive pairs at different elevations, a common water main, each pair of pumps comprising two cylinders having suction and discharge connection with the water main; a cut-off valve in each suction connection, a by-pass for the main pipe having a cut-off valve therein; a piston in each cylinder having a rod extending through a stuffing-box in the upper end of the cylinder, two power-transmitting rods extending alongside of the corresponding cylinder of each set; connections from rods to piston rods and means for giving the power-transmitting rods alternate or opposite reciprocations.

ORE CONCENTRATING TABLE.—No. 621,515; F. L. Bartlett, Canyon, Colo.



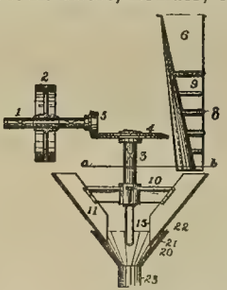
An ore concentrator, longitudinally reciprocating shaking table, with a series of laterally inclined shelves provided with longitudinal riffles extending to the concentrates discharge end thereof, whereby the concentrated material is discharged at the end of each shelf, a separate water supply for each shelf and means for conveying the unconcentrated material from each shelf except the last to the next shelf in the series. The series of laterally inclined shelves are arranged at descending levels. There is a spout extending along the lower side of each of the upper shelves except the last two for delivering the unconcentrated material to the upper side of the next shelf below. The shaking table has longitudinal riffles adapted to discharge fine material over the end of the table and coarse material over the side, and a series of sliding conductors under the discharge end of the table.

ANTIFRICTIONAL ATTACHMENT FOR WATER OR OTHER GATES.—No. 621,566; John H. Hendy, San Francisco, Cal.



A gate movable transversely across the passage which it controls; a screw-threaded non-turnable stem connected therewith; an elongated nut, through which the threaded part of the stem passes; a hand wheel by which the nut is turnable, an outwardly projecting annular flange around the periphery of the lower end of the nut, a chambered cap within which the flange is turnable and balls disposed between the opposite sides of the flange and the adjacent sides of the chamber. There are annular removable disks grooved or channeled to coincide with the grooves or channels on the flange of the nut, fitting the upper and lower parts of the chamber and a series of balls fitting the grooves and forming a bearing for the flange.

ORE SAMPLER.—No. 612,771; C. A. Snyder, D. J. Cheesman and J. A. Moore, Boulder, Colo.



An ore sampler, combination with a shaft rotating on an upright axis, a series of buckets carried thereby and having open mouths at their upper ends and a hopper into which they deliver; of a chute delivering a stream of material substantially parallel with the shaft, its delivery end standing above the path of the bucket mouths and being curved to conform with their movement, and a series of irregularly arranged bolts across the chute. The upright chute has converging side walls, its delivery end being curved in a horizontal line; the upright rotary shaft stands concentric with the curvature of the end of the chute, a spider on the shaft, a series of buckets carried thereby and each having a substantially U-shaped cutting edge at its upper end which latter stands below the delivery end of the chute, the length of such delivery end being such that as one bucket passes from beneath it another enters at the other side thereof, and a hopper for receiving the samples taken by the buckets.

What a Mile a Minute Means to the Locomotive Making It.

At sixty miles an hour the resistance of a train is four times as great as it is at thirty miles—that is, the fuel must be four times as great in the one case as it is in the other. But at sixty miles an hour this fuel must be exerted for a given distance in half the time that it is at thirty miles, so that the amount of power exerted and steam generated in a given period of time must be eight times as great at the faster speed. This means that the capacity of the boiler, cylinders and the other parts must be greater, with a corresponding addition to the weight of the machine. Obviously, therefore, if the weight per wheel, on account of the limit of weight that the rails will carry, is limited, a point is soon reached where the driving wheels and other parts cannot be further enlarged, and then the maximum of speed is reached. The nice adjustment necessary in the various parts of these immense engines may be indicated by some figures as to the work performed by these parts when the locomotive is worked at high speed.

Take a passenger engine on any of the big lines. At sixty miles an hour a driving wheel 5½ feet in diameter revolves five times every second, so that the reciprocating parts of each cylinder, including one piston, piston rod, crosshead and connecting rod, weighing about 650 pounds, must move back and forth a distance equal to the stroke (usually 2 feet) every time the wheel revolves, or in the fifth of a second. This weight starts from a state of rest at the end of each stroke of the piston and must acquire a velocity of 32 feet per second in one-twentieth of a second, and must be brought to a state of rest in the same period of time.

A piston 18 inches in diameter has an area of 254½ square inches. Steam of 150 pounds pressure per square inch would therefore exert a force on the piston equal to 38,175 pounds. This force is applied alternately on each side of the piston ten times in a second.

The Mule Must Go.

In the anthracite coal regions of Pennsylvania the edict has gone forth that the mule must go. The Philadelphia & Reading Coal & Iron Co. is preparing to introduce the air compressor locomotive as a means to haul the cars underground at Shenandoah City colliery. Ever since the first coal hole was sunk the mule has been the favorite means of locomotion in moving the coal. He turned the gin at the top of the slope; he pulled the cars of dirt and rock out into the dump, and he felt his way along the narrow gangway at the head of a string of cars. It was about a year ago that the company first began to make preparations for this change. Alaska colliery near Mount Carmel was selected as the place for making the experiment. The necessary changes were made and the machinery secured. The air compressor engine has been working there for some months, and has been a success. The new method of hauling is used in only one part of the mine. The distance is one mile, and the new engines draw twenty-five cars on each trip. Seventeen mules have been thrown out of employment. It is not only that the company expects to save in the cost of mules and their maintenance, but the cost of feed, the smithwork and other expenses are also saved, while at the same time the mine cars are moved with greater speed, adding in that way to the capacity of the colliery. For some years the coal regions have been the most extensive markets for the mule dealers. The soft coal districts also use mules. Over 15,000 mules are at work in the hard coal mines. The price of mules runs from $90 to $125 a head. Averaging the cost at $100 gives a total investment of $1,500,000 in mule flesh in the anthracite coal region.

In a recent lecture at the Royal Institute, Sir Robert Ball, the eminent astronomer, stated that we now know the existence of 30,000,000 of stars or suns, many of them much more magnificent than the one which gives light to our system. The majority of them are not visible to the eye or even recognizable by the telescope, but sensitized photographic plates have revealed their existence beyond all doubt or question, though most of them are inconceivably distant, thousands or tens of thousands of times as far off as our sun. A telegraphic message, for example, which would reach the sun in eight minutes, would not reach some of these stars in 1800 years. An average of only ten planets to each sun indicates the existence within the narrow range to which human observation is still confined of at least 30,000,000 of separate worlds, many of them doubtless of gigantic size, and it is nearly inconceivable that those worlds can be wholly devoid of living and sentient beings upon them, probably mortal in our sense, illustrating the insignificance of mankind.

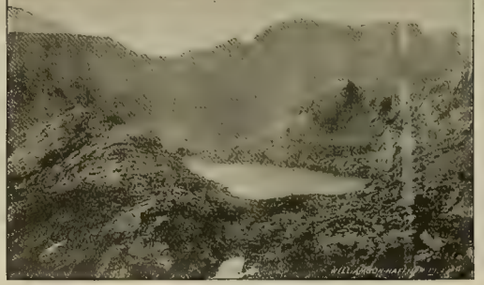
The introduction of a bill in the recent U. S. Congress brings to mind a singular omission in the Patent Laws. Heretofore, if an applicant entered his application and chanced to become deranged between that time and official action on the claim, he was left to the mercy of his malady, and no patent could be issued. The bill referred to provides that in cases of this kind the legal representative of the applicant may prosecute the case to final decision.

Irrigation in Wyoming.

Irrigation is a pleasant subject: the longings of mankind naturally turn to lakes, reservoirs and streams, and desire burns strongly for water supplies which shall insure independence of fickle seasons in this west half of America. Elwood Mead, State Engineer of Wyoming, sends a copy of his Fourth Biennial Report, covering the years 1897-8, a business-like document with records of what is actually being done in the extension of irrigation in that State. Some idea of the exactness of the report as a record of business done in the office of the State Engineer can be had from the fact that there are 2009 permits to appropriate water recorded, each with the name of the appropriator, the stream or other source, the dimensions of the ditch, the cost and the number of acres to be irrigated. There are also records of several hundred applications to enlarge earlier appropriations. These facts show that the use of water in Wyoming is proceeding rapidly and that it is proceeding under State regulation which befits the interest of small irrigators as well as large, as the records show permits issued to very large numbers of men with comparatively small holdings of land.

Lake on Ten Sleep Creek Wyoming.

Lake on Prairie Dog Creek, Wyoming.



Lake on Clear Creek, Wyoming.

Kearney Lake, Wyoming.

IRRIGATION SCENES IN WYOMING.

Wyoming seems in the van of the movement for reservoir construction by the United States. Surveys have been fully made and reports showing the facts about construction are in the possession of the Government, affording a place to begin the reclamation of the great waste region of the West and a vantage which is being strongly urged by those who support the contention that the general Government should do something for the improvement of the interior as well as for the harbors and navigable watercourses. This matter has been forcibly brought to the attention of Congress during the present winter by the efforts of G. H. Maxwell and others representing the National Irrigation Congress, and if it wins its way ere long it will mean the extension of the same policy to the whole arid and semi-arid region of the country. This general proposition is also receiving the most earnest promotion of Mr. Mead of Wyoming and his work commends him.

Mr. Mead's report is finely illustrated. Herewith is reproduced four of his plates which show a number of the sites in the State of Wyoming available for reservoirs, of which the report shows a large number, with maps and details of value to the practical developer of irrigation facilities, for mining and other purposes in which water supply is needful.

The New Nernst Lamp.

What has been termed "the greatest invention in electric lighting for many years" is the new electric incandescent lamp known as the Nernst lamp. The inventor uses highly refractory oxides as his material, heating the rods so as to make them conduct and then heating them electrically. The material is worked up into little white rods, and each mounted on two platinum wires and in a holder which fits ordinary electric-light fittings. An increase of current produces a decrease of resistance, since the rods fall in resistance as the temperature increases, after the manner of electrolytes. A series resistance, however, corrects this instability in running in parallel on supply circuits. This resistance is made up of exceedingly fine wire, having from 10% to 12% of the whole resistance of the lamp. The consumption per candle for large lamps is 1 5 watts and for small lamps or low pressures is 1.6 watts. Since the rod is an insulator when cold, this lamp will not light of itself and the simplest way to start it is to warm it up first with a match, or better still, with a small spirit lamp. This lamp is not only cheap as regards first cost, but is economical in running. At an efficiency of two-thirds of a candle per watt, including the resistance, the life of the rods is more than 500 hours in good specimens. When a rod is worn out, a new rod with its wire mounts is all that is replaced. In lamps of from 20 to 200 c. p. in which it would pay to have automatic ignition, the first cost will be higher than the first cost of incandescents, but as the rods only have to be replaced, the higher first cost is of minor importance. These lamps may be worked at a pressure of 500 or, by using double rods, even 1000 volts if desired. In regard to cheapness, renewals, high efficiency, better colored light and high pressures, the Nernst lamp is said to far excel the carbon incandescent lamp.—The Engineer.

One lesson which the Spanish-American war has thoroughly taught is the vital importance to a nation which would have an efficient navy of the fostering of the mechanical instinct. Americans may be proud of being a nation of mechanics and I attribute the overwhelming victories over the Spaniards largely to this fact and the absolute lack of any mechanical aptitude on the part of the opponents. The utter failure of Cervera's fast armored cruisers, which had trial speeds of twenty knots, to escape from the United States vessels at Santiago, none of which were making seventeen, shows the disastrous results of discouragement of the mechanic. As we know, the condition of the two fastest ships at Santiago—the New York and Brooklyn—was such that only half-power could be used immediately, and it seems almost certain that, had Cervera's ships been able to make their maximum speeds, they would have escaped.—Engineer-in-Chief G. W. Melville, U. S. N., in the Engineering Magazine for March.

United States Commercial Agent Atwell has submitted to the State Department a report on the French development of wireless telegraphy. Practical work in this line is now being done in Paris, where a line is in operation, sending messages a distance of two and one-half miles. A special radioconductor, known in this country as the Branley tube, takes the place of the ordinary soft iron magnet. The special receiver is operated from the sending station, with no other conductor but the atmosphere. The message is recorded at the receiving end by the old tape method, long ago discarded in this country. The sending station is equipped with a mast 65 feet above the laboratory, so as to escape iron-constructed buildings. The system can be used to explode mines at a distance, or even to operate a distant electric light, the only question being that of obtaining sufficient power.

The Alluvial Deposits of Western Australia.*

NUMBER V.—CONCLUDED.

By T. A. RICKARD, State Geologist, Denver, Colorado.

The water supply of the region comes from two sources, namely, that which has collected amid the purely superficial deposits of debris and drift covering the actual rock surface, and, secondly, that which has penetrated the decomposed rock down to the zone where oxidation ceases.

Wherever a depression occurs the prevailing rocks, granite and diorite, are overlaid with a variable thickness of their own detritus, which allows the collection of rain water and affords protection from too rapid evaporation. These are known as "soaks." At Hampton Plains, eight miles from Coolgardie, a supply of condensing water has been obtained from beds of this nature. During the wet season some of the depressions filled with such accumulations of detritus will receive more water than they can hold, and then the eye becomes gladdened for a few days by the sight of water running over the surface. As it becomes diminished by evaporation it disappears from view, but will be found to linger in the rock holes, where the supply is maintained by the slow drainage of the surrounding porous area. These are called by the aborigines "guamma" holes. The life of such natural wells depends, of course, on the water-bearing depression and upon the relative porosity of the deposit which it drains.

These supplies are in their nature uncertain. The next and more important source of supply is found at the ordinary drainage level of the country, namely, the horizon where the oxidation of the surface ceases and the relatively hard unoxidized rock offers a partial barrier to the free descent of the waters which have percolated through the overlying formation. The depth of this zone will depend upon the permeability of the superficial rock formation; it varies from 40 feet at Earlston to 202 feet at Kalgoorlie. A characteristic section is that given by the well put down on Reserve 3096, Coolgardie, where the Goldfields Water Supply Department sunk 165 feet and found 7 feet of sand, 47 feet of conglomerate and 111 feet of decomposed granite. The water was found at the base of the last, just above the unaltered granite.

Condensers.—Frequent mention has been made of the condenser. This is a characteristic feature of every mining settlement in the interior of Western Australia, and occupies the position accorded to the public well of a European village. Without this process of distillation, which renders the brackish water of the wilderness fit for human consumption, the mining industry could never have progressed beyond the merest prospecting.

The introduction of condensers is traceable to the sailors who took a prominent part in the early exploring expeditions. When the rush to the new goldfields occurred the Government, by erecting condensers at intervals along the main lines of travel, did much to diminish the loss of life otherwise inevitable in times of wild excitement by reason of the recklessness of those who joined the stampede without due care for the great necessity of life in a tropical desert.

The process of converting brine into drinkable water is simple. The salt water is put into a boiler and converted into steam, which is then condensed in vessels presenting a maximum of cooling surface. Ship tanks, having a capacity of 400 gallons, are commonly employed as boilers, and the condensing apparatus is constructed out of the corrugated iron which is everywhere employed for roofing purposes. The tanks used as boilers are usually set on edge in pairs, as shown in Figs. 17 and 18. The average product of each 400-gallon tank is about 300 gallons of distilled water daily. Two vertical short iron pipes draw off the steam, which passes into condensing chambers or "coolers." The latter were originally plain circular tanks, which were increased in capacity by the addition of sections, increasing the height. Sheets of corrugated iron were bent round until the ends met, and these were united by riveting and soldering. Several such sections were united, and a tubular tower about 30 feet high and 3 feet in diameter was the result. The top and bottom were closed by a flat sheet of iron. A 6-inch pipe connected the towers, and steam traveled up the one tower and down the next. (See Fig. 19.)

This type has been superseded of late by annular chambers. An outer corrugated iron cylinder 2.5 feet in diameter surrounds an inner 1.5-foot cylinder, so as to leave an annular space 6 inches wide, which becomes the condensing chamber. No attempt is made to suppiement the cooling effect of the surrounding air, though a brush shelter is sometimes erected so as to ward off the direct rays of the sun.

The daily expenditure includes the labor of two men, one on each shift, and the cost of the fuel consumed. A typical condenser is that erected on the Lake View & Boulder Junction mine, shown in Fig. 20. This plant has a capacity of 1500 gallons of condensed water per day and cost £100. The water treated comes from the mine and shaft and has a specific gravity of 1.03385, the total solids amounting, according to the analyses of Mr. E. S. Simpson, to 4.9308% and the chlorine to 2.3933%. The cost averages, during the cool season, 5 shillings, and during the summer 6.5 shillings per hundred gallons of condensed water. The condensed water is sold at from 10 to 12 shillings per hundred gallons. A first-class condenser would consist of at least eight boilers, each having 400 gallons capacity and a daily output of 300 gallons of condensed water, giving the plant a daily yield of 2400 gallons. The salt water is usually bought for from 2 to 4 shillings per thousand gallons. Fuel costs 20 shillings per cord and is consumed at the rate of one cord per thousand gallons of condensed water. Thus the cost would be:

	Shillings.
2 men at £4 per week of 6 days	27
2½ cords of wood	50
3200 gallons of salt water	10
Total	87

This would be at the rate of 36 shillings per thousand gallons. During November '97, condensed

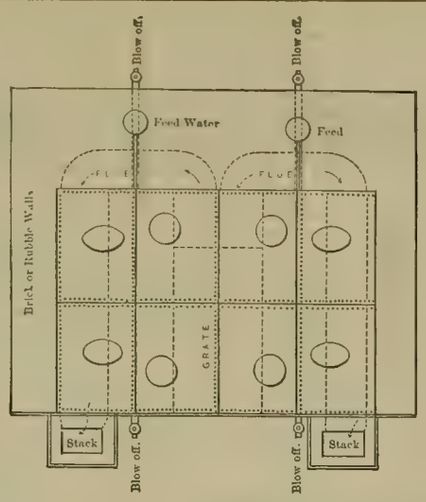


FIG. 17.—PLAN OF ORDINARY CONDENSER.

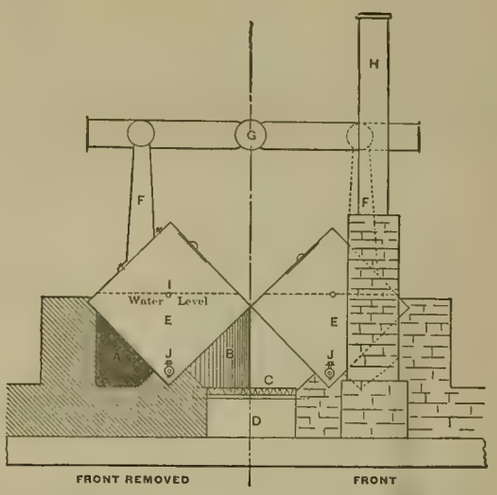

FIG. 18.—SECTION AND ELEVATION OF CONDENSER.

FIG. 19—BUYING WATER AT A CONDENSER.

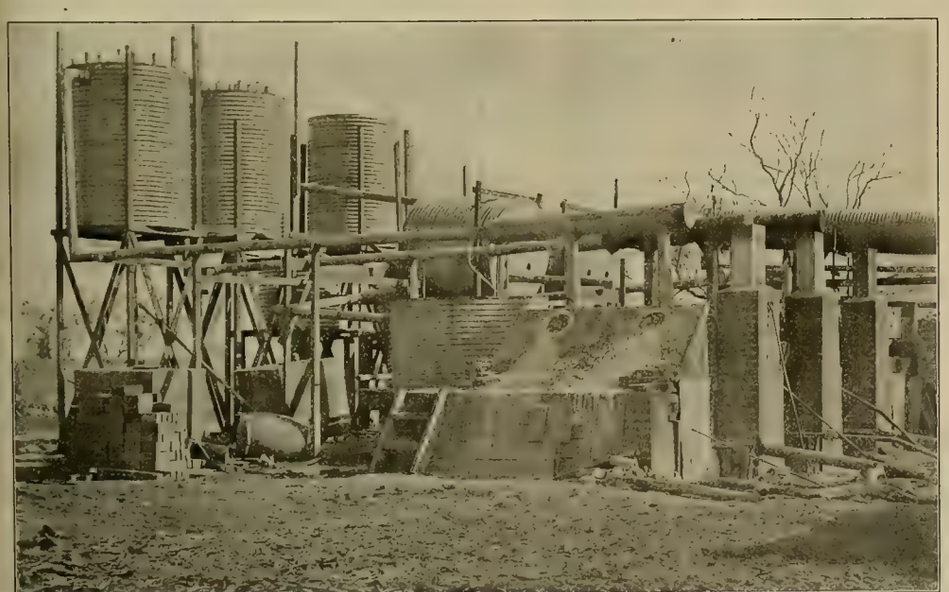

FIG. 20.—CONDENSER AT THE LAKE VIEW AND JUNCTION MINE, KALGOORLIE.

*Condensed from paper read before the Am. Inst. M. E.

water sold for 100 to 150 shillings per thousand gallons.

Concerning the use of salt water in the stamp mills and leaching works of Western Australia, I would say that its density is an obstacle to amalgamation because of the facility with which slimes are created. The finer particles of gold are thus prevented from settling on the copper plates of the tables, and are carried away in the tailings. At Kalgoorlie the cyanide works use the natural brine successfully, its magnesia being precipitated by lime, so as to prevent the decomposition of the stock solution.

In order to aid the development of the mining industry, which is still severely handicapped by the want of a sufficient supply of water, the government of Western Australia has decided to carry out a hydraulic enterprise of great magnitude. It is proposed to supply 5,000,000 gallons of fresh water per day to the Coolgardie goldfield by building a pipe line from the Darling range, where the Helena river will be impounded by a concrete dam 100 feet in height and 650 feet long. The source of supply is 320 feet above level, while the service reservoir at Coolgardie will be on Mt. Burgess, at a height of 1670 feet, or 1350 feet higher. These two reservoirs will be connected by 330 miles of 30-inch steel pipe. Nine pumping stations will be required. The appropriation for this work is $12,500,000. The annual operating expenses will probably approximate $1,600,000, and water will be delivered through a hundred miles of distributing pipes at a cost of 3 shillings and 6 pence, or 84 cents, per thousand gallons.

It will occur to the reader to ask whether boring for artesian wells has been attempted. Yes; in obedience to the public demand the Government put down a bore at Coolgardie which reached a depth exceeding 2000 feet and found—granite. The geological conditions render an artesian flow of water highly improbable. Nevertheless, in this colony, as elsewhere among the arid tracts of Australia, there is a whispered hope of finding a subterranean river. As the Carson and the Humboldt are swallowed up by the alkali wastes of Nevada, so in the desert plains of this southern continent there are many streams which flow into the interior and lose themselves in the sand or find for themselves an underground channel. This occurs in Queensland, where the geological conditions are quite different. Several very successful boreholes have been put down, an abundant artesian flow being obtained at depths of 2000 feet and over. This fact has given rise to conceptions, more poetic than scientific, of a great subterranean river yet to be discovered, and destined in days to come to make the desert break forth into fertility. It is a dream. No irrigation can turn the wastes of quartz sand into waving fields of wheat. Time, geological time, covering a period to measure which the duration of a man's life is an inadequate unit, can alone render the wilderness fit for human habitation.

Hardwood Veneers.

The use of South American rare hard woods is extending into many new fields and uses. The perfection of veneering machinery by which very thin slices of the wood can be cut off at half the former prices enables cabinet and furniture manufacturers to turn out loads of mahogany articles. These furniture articles are what the trade calls "built-up" furniture. That is, they have a core of white pine or other cheap wood, and the surface is then veneered with thin layers of mahogany. Before the veneering machinery was invented all veneers were hand sawed, and they cost considerable; but to-day 75% of the veneers are cut or sliced by huge knives. The sawed veneers are much better than the cut, and they last longer, but for the cheaper grade the cut answers all purposes. The slicer, as the veneer-cutting machine is called, is a costly machine, but it performs its work with wonderful effects. A large mahogany log is put into the powerful grip of the slicer, and as it moves against a rigid knife, which is 17 feet long, the veneer is cut off as evenly as a shaving is sliced from a block of wood by a plane. The whole log is thus sliced up into veneers $\frac{1}{30}$ inch thick. Thus one log may yield several hundred veneers. Sawed veneers are more expensive because not more than ten to fifteen can be cut from an inch of wood. The rest of the wood is lost in sawdust, while in the cut veneers there is no waste at all.

BY his will the late Alfred Nobel, the Swedish dynamite manufacturer, left almost the whole of his fortune to be converted into an international fund for the advancement of scientific research. The bequest, however, was disputed by the relatives of the deceased, and litigation ensued. It is now announced that a compromise has been reached, whereby the relatives receive about $1,000,000 of the property, the balance, amounting to about $7,000,000, being used as designated by Mr. Nobel. This will give, under the terms of the will, five prizes annually of about $41,000 each to persons making the most important discoveries in physics, chemistry, physiology and medicine.

The Crosshead and Bucket in Vertical Shafts.

Written for the MINING AND SCIENTIFIC PRESS.

When sinking in vertical shafts or, as is often the case in small mines, ore and waste are hoisted in buckets from the several levels through a vertical shaft, the work is greatly facilitated and the likelihood of accident reduced by the use of guide rails and crosshead. These cost but a small sum for lumber and placing in the shaft—about 10 cents per foot—and afford such additional security as to make them desirable regardless of the expense. The guide rails may be made from selected pieces of 3x4-inch scantling, cut in lengths to take in three full sets of timber, each set of guides meeting at the center of the wall plates and dividers. They should be planed and straight. The guides can be best secured to the end plates and center piece of the shaft by 6-inch lag screws, counter-sunk below the face of the guide. It is not necessary that the guide rails should be let into the shaft timbers, but will be perfectly safe if properly secured as suggested. The ends of the guides may butt flush or may be made additionally secure by cutting a tongue and groove in the ends, having a lag screw both above and below the joint, as shown in Fig. 1.

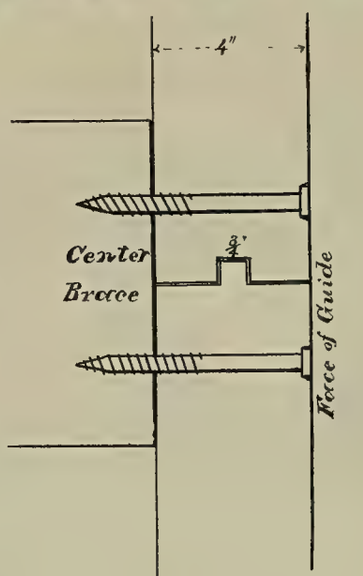

FIG. 1.

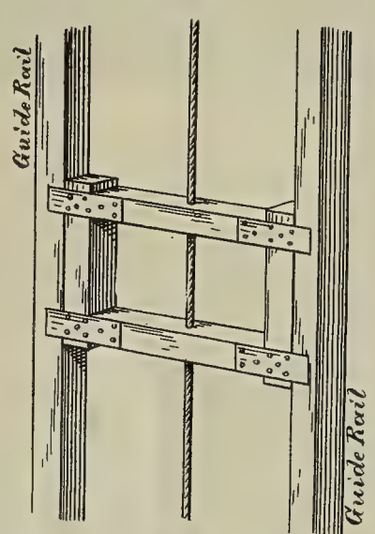

FIG. 2.

The crosshead (Fig. 2) should be built of 3x4-inch scantling, mortised and firmly bolted. Its width should equal the distance between the guide faces, allowing sufficient space for free movement. For instance, in a shaft 4 feet across the compartment the guides will take up about 7¾ inches of the space, after planing. The crosshead frame should then be 39¾ inches wide. The corners, top and bottom should be beveled to obviate the likelihood of catching slivers of wood or slight obstructions. The crosshead should have a depth of not less than 24 inches to secure steadiness when in motion, and the faces may be shod with iron plates which lap around the sides of the guide rail, or flat iron plates may be screwed to the sides of the crosshead frame, extending 3 inches beyond the frame, so as to inclose two sides of the guide rails. The crosshead is secured to the cable by use of wooden wedges, driven sufficiently tight to prevent slipping under all ordinary conditions, yet not so firmly as not to permit the crosshead moving in case of overwinding, serious consequences from which the crosshead is quite sure to prevent. To insure against the crosshead dropping upon the bucket, thereby injuring workmen or causing other damage, a "stop" in the form of a short piece of cable secured by clips may be placed upon the rope 8 feet above the bale of the bucket, out of reach of the men. The crosshead should be fastened not less than 10 feet above this stop, which will afford a good run in case of accident—overwinding, etc. Often the timbers in a shaft do not extend nearer than 15 to 20 feet from the bottom, unless the character of the ground be such as to require that it be carried down close, but placing the crosshead as above suggested admits of having the bottom of the guide rails about 20 feet above the bottom of the shaft. A sufficient factor for safety should be allowed, so that it will be impossible for the crosshead to drop clear of the guide rails. Near the bottom of the shaft it will be found desirable to use short sections, which are replaced by the long permanent guides when a sufficient distance has been made in sinking.

The use of the crosshead requires a higher gallows-frame than where no such device is employed, but it will be found an economical investment in the long run.

Small Reservoirs.

The proper way to irrigate small tracts of land is to do it from a reservoir. One cannot do much with a small stream of water and it will not pay to have a large plant and put it in operation for a small tract. A small pump can be kept in operation all the time cheaper than a large one occasionally. A reservoir should be built on the highest part of the tract sought to be irrigated and a small engine set to work filling it. The reservoir is built by scraping the earth from the outside and, of course, from such a large area as not to affect the utility of the land from which it is taken. With a levee all around 5 feet high 4 feet of water could be carried safely. The slopes ought to be two to one on the inside. A reservoir 20 feet square and 4 feet deep would hold 12,000 gallons. With the slopes as above the reservoir should be measured 2 feet from the bottom, or half way up the 4 feet of water; consequently to lay out a reservoir to hold 12,000 gallons put the stakes 12 feet square and build. For any other sized one take 8 feet off the same as in this. A reservoir 25 feet square will hold 18,750 gallons and would be 17 feet square at the bottom; one 30 feet square would hold 27,000 gallons and would be 22 feet at the bottom; one 35 feet square—27 at the bottom—will hold 36,000 gallons; one 40 feet square—32 on the bottom—will hold 48,000 gallons. Almost any of the land on the river or out on the plains will hold water with a little puddling. The cheapest way to puddle is to build a pen the size of the intended reservoir, including at least a portion of that to be under the embankment, wet it very wet, put some hogs in the pen and keep feeding them a little barley at a time, so as to make them not only walk around but root for the barley. A half sack of barley fed to eight or ten hungry hogs in half a day will make a good puddle. (This is about the only way a hog can be made to do useful work!) This could be tried and if it did not work satisfactorily the water could be taken off and the bottom covered about an inch deep with coarse sand mixed one part to five with Portland cement, put in dry, and let it be covered slowly. A barrel of cement may be counted at about 4 cubic feet and with the mixture above would cover the first-named reservoir about 1¾ inches. This would make it "jug tight." The supply pipe should come up from the bottom, so that the lift would never be more than the height of the surface. The cheapest power is of course the windmill, but for many purposes it is not reliable enough. Next to this is the small gasoline engine.

THE English torpedo boat, the Turbinia, credited with a speed of thirty-five miles an hour, may be surpassed by an American inventor, L. H. Towns of College Point, L. I., who announces the building of a boat that will go forty-five miles per hour. The new boat is to be 70 feet long, 7 feet wide, fitted with a 1000 H. P. carbonic gas motor; the engine, with three cylinders, to have a working pressure of 2000 pounds to the square inch, and, as there will be no boiler, and all the tubing is under the floor, no unnecessary space will be occupied by machinery. The engine is to be an upright one, with the piston action up from the cylinder.

THE restrictions placed upon California hydraulic mining resulted in the creation of a system of recovering gold from the old river channels which is known as drift mining. By this method long galleries are driven along the bedrock in the gravel and the gold bearing material extracted where it is richest—along and near the bedrock. This method of mining has proven very profitable in many cases and it has some features which make it a very desirable method. The environments of hydraulic and drift mines are very important considerations in determining the amount of capital necessary to accomplish a definite result.

Mining Summary.

ALASKA.

It is reported that not less than 3000 men will be at work in the Porcupine country this summer. Porcupine includes Clear Creek and Akkuk Lake country, and is on the American side of the boundary. Quartz veins are being located in the district.

Juneau has a sampling works for testing ores.

Americans are still rushing into the Atlin Lake country regardless of the Exclusion Act.

Another strike has been made driving a tunnel between the Bald Eagle and the Sumdum Chief mines at Sumdum. A rich ledge was struck.

Juneau *Mining Record*: The Gold Commissioner for Atlin Lake district has issued an order that all claim holders must be on their claims by April 1st.

ARIZONA.

(Special Correspondence).—Mining in northwestern Mohave county is increasing, and many sales have been consummated since the advent of '99. Chloride is now the most active and prosperous camp of this part of the country. The two prominent lead mines are the Elkhart and Tennessee. Both have large mills running and are shipping quantities of good lead ore. The Elkhart is owned by a Scotch company and the Tennessee by a Los Angeles company.

A valuable silver mine is the Distaff, owned by C. E. Sherman. It is being worked now by leasers, who are shipping high-grade ore.

The Merrimac, lately sold for $9000, is working a force of men and producing high-grade ore.

The Mollie Gibson, together with two adjoining claims, was sold in February for $17,000 to an Eastern company, which is preparing to erect a concentrator, boarding house, etc., and develop the property.

The copper mine owned by John and Kean St. Charles is being negotiated for.

Among the other mines working are the Tintic, Juno, Minnesota and Connor, owned by J. Barry, and the Rainbow, West Virginia, Lucky Boy, Conova and others, which are being worked by owners and leasers.

Other valuable and working mines are situated at White Hills, Mineral Park, Todd Basin and Cerbat.

Mineral Park, March 22nd, '99.

The lead mines of Castle Dome, on the Colorado river above Yuma, are being worked by E. F. Sanguinette of Yuma.

Yuma *Sun*: The King of Arizona Co. near Yuma is putting in a 100-ton cyanide plant and is prospecting for water in the valley. They propose to sink a well 2000 feet deep, and if sufficient water is not found a pipe line from the river will be put in.

Prescott *Courier*: A strike in the Hassayampa district is reported of a ledge 1 foot wide which assays $300 to $750 per ton gold, and twenty-six ounces silver. The mine is the Tip Top, owned by Shull & Phillips of Prescott, who own the Orphan Girl, the first extension of the Tip Top.

CALIFORNIA.

Amador.

Amador *Record*: The Lincoln shaft is down 862 feet and sinking at the rate of 10 to 12 feet a week. The shaft will be sunk to 1200 feet before opening up new levels. A crosscut is being run north at the 500 level. Twenty-three men are employed.——Supt. F. Walker started up the Reward mine, near Pine Grove, last Saturday, and is taking out the water and driving the tunnel.——In the same district D. Fisher is removing a hoist from the Wieland to the Spagnoli mine.

Amador *Dispatch*: The miners sinking the shaft in the Central Eureka mine are credited with having deepened the shaft over 50 feet a week.

Calaveras.

Amador *Record*: The Gwin mine has let a contract to the Union Iron Works of San Francisco for a 40-stamp mill.

Calaveras *Prospect*: The Jupiter gravel mine at Dogtown is working twenty-five men. ——The work of unwatering the Carson Creek mine, five miles south of Angels, is nearly finished and work will commence soon.

Angels *Echo*: A. Lee of Angels has been awarded the contract to build a 125-stamp mill on the Melones mine, at Robinson's Ferry.

Echo: It is the intention of the company having the Bald Hill mine, 2 miles south of Angels, under bond to put the main shaft down to 500 feet. The present depth is 120 feet.——Twenty men are employed on the Fox mine at Angels under the superintendency of T. Fleming. It is said a 40-stamp mill will soon be built.——J. Lotre of Italian ranch will place a 4-stamp mill on his mine on San Antone creek. It has been constantly worked for the past two years and is well developed. ——The Round Butte gravel mine has started up since the rain.——Campbell & Elliott discovered a quartz lead about 2 feet wide on the San Antonio ridge two miles from Sheep Ranch.——The cleanup at the Rose Hill mine near El Dorado proved satisfactory. L. Emery, owner of the property, has ordered new steam machinery for the mill. The rains have assured a supply of water for other power. They have spent $60,000 in repairing a reservoir and ditch and laying pipe to bring water to the mine. The water will be used for power and also for hydraulicking a large tract of placer land in connection with the Rose Hill property. Mr. Emery is erecting a large building on the road about one and one-half miles from El Dorado.——The Alpine and Extension mines, recently bonded to the Rose Hill Co. for $20,000, are being developed.——The Martha mine, an extension of the Ritter, near El Dorado, is being prospected. Development shows 600 feet of lead having an average width of 2 feet.——It is reported the Live Oak mine, owned by Tiscornia & Co., was recently bonded.

Del Norte.

(Special Correspondence). — San Francisco capitalists are running a tunnel several hundred feet long on the property of the Jones Creek M. Co., prospecting with a view to purchasing.——Gates & McMurray have put men to work on the old Union copper mine. They will ship ore to San Francisco.——Bailey & Chase are at work on their copper claims on Smith river, getting out ore for shipment to San Francisco.——Parties from San Francisco have located copper claims on Shelly creek, near the State line, and are getting some fine gold for shipment.——Grider & Deitrich are developing their cinnabar property on Diamond creek. They also have some very rich copper prospects in the same locality.——Mangum, Booth et al., of Grant's Pass, Or., have located several hundred acres of placer ground on the Siskiyou Fork of Smith river. ——Jenkins Bros. & Lewis are now running their arrastra on Myrtle creek. They have a prospect of developing a paying property, having free milling ore that assays from $13 to $150 per ton. This is the first systematic effort at working quartz made in the county. ——The late rains have insured sufficient water for a long season in operating the placer mines on Smith river and its tributaries.

Myrtle Creek, Cal., March 20th, '99.

Del Norte *Record*: J. Holloway recently brought into Crescent City from the South Fork of Smith river, as a result of twelve days' run, $50 in gold, mined by himself and partner. A shortage of water prevents steady work and big results.——J. Murray has gone with a crew of men to develop the Union copper mine at Low Divide.

El Dorado.

Mountain Democrat: The Crown Point mine is in operation again.——Numerous claims are being located in various parts of the county. ——The El Dorado Power Co. has been incorporated, for the purpose of supplying mines and other industries with power.

Fresno.

(Special Correspondence). — The mineral belt extending southward from Mariposa county through Madera enters and continues through Fresno county and is characterized by the same class of mineral veins. The formation is mica schist and granite, the ores usually high grade. There are also ancient river channels in this county, similar to those farther north in Calaveras and Tuolumne and capped with lava, and although good prospects have been obtained in gulches heading up in these old channels very little has been done to test the channels themselves. This kind of mining is not understood in this section and consequently is given no attention. There is abundance of timber and water and good fall, in fact, every condition to assist in the economical handling of these channel mines. No one can say they will not pay for the reason that no one has ever given them a trial.

Pollasky, March 24th, '99.

Inyo.

There is a wide field for the prospector in this county. The mines include gold, copper, silver and lead. In early days, when conditions were more unfavorable than now, mines were successfully worked here. Considerable prospecting is now going on near Darwin and in other localities with encouraging results.

Kern.

J. H. Underhill of the Butte mine at Randsburg has sold his interest in the property to W. H. McEwen of Los Angeles. The mine is credited with a production of $130,000.

Veins containing gold, silver and copper have been located near Red Rock.

Randsburg *Miner*: The Little Butte mine is taking out some rich ore and the outlook for that company is better than for some time past. They have paying ore in nearly all their levels.——The Yellow Aster Co. is putting up a large oil tank made from ¼-inch iron at the end of the track in Johannesburg. It is to be 12 feet high by 21 feet in diameter and will hold over 35,000 gallons. The oil will be pumped from the tank to the tank at the mill.

Los Angeles *Times*: In Fiddler's Gulch, at Randsburg, is a 15-foot ledge of ore, all of which prospects.——Out toward the Black Hawk, M. P. Minor is getting ore from the Golden Glance mine, and there are three or four additional properties that prospect well. ——Atkinson, on the Sunshine, recently milled five tons which went $200 per ton.——The new mill at the Black Hawk is ready to run. Their pipe line is in and the water connection made. This mill was formerly at Cuddaback lake.——In the Slate Range there is activity among miners and a number of prospects are being developed. Pridham & Quinn of the Eureka mill have associated E. M. Dineen with them and have removed their cyanide plant to Montgomery's, in Pleasant canyon, about four miles above Ballerat, in the Panamint country. There is a pile of tailings estimated to contain $20,000, after working which there are several other piles in that neighborhood to work. Their stamp mill will remain in Randsburg, to which place their cyanide plant will be returned after the work is finished at Panamint.——There are a number of good houses going up at Randsburg. Among them the Miners' Union is building a hall, 30x70 feet.

Lassen.

The rich strike in one of the Hayden hill mines will stimulate prospecting in this county and new discoveries may be looked for. There are also gold-bearing gravel deposits in the county, to which little attention has ever been given.

Los Angeles.

Four miles up the valley from Acton station is a quartz vein nearly 100 feet wide on which only superficial work has been done. The rock is gold-bearing.

The occurrence of an ancient gravel deposit, said to be a river channel, containing coarse gold, on Mount San Antonio, at an altitude of more than 8000 feet, furnishes a subject for geological investigation. The placers have been worked each spring for many years with good results.

The New York mine, near Acton, which was steadily worked for years, it is reported, will be reopened.

A recent run at the Red Rover mill yielded $1300 from 115 tons of quartz. The quartz in these mines—the Red Rover, New York and Old Topeka—is white fine granular and contains a low percentage of auriferous iron sulphide. Gold is rarely seen in the rock. The values run quite evenly from $10 to $15 per ton.

The discovery of a 5-foot vein of quartz which assays $6 per ton is reported from Calhuenga pass, north west of Los Angeles.

Mariposa.

Wolframite (iron tungstate) is said to occur about twenty miles south of the town of Mariposa, near the old Buchanan copper camp, and not far from the Chowchilla river.

Zinc ores occur in considerable quantity in the mines on Mt. Raymond, five miles east of Fish Camp. These mines were operated about ten years ago, and a large concentrating plant and wire tramway built. After a short run the mines were closed down, probably because the zinc predominated over the lead. The ores also contain silver. The ore bodies are large and occur in diorite. The development is superficial, consisting of several open cuts and short tunnels run from them. No systematic development has ever been undertaken. These deposits lie in the belt which runs along near the crest of the high Sierras, and of which but little is known, being opened at only a few points.

Nevada.

Grass Valley *Union*: The machinery has been ordered for the mill to be erected on the St. Patrick mine, which will arrive when the roads get better.

Nevada City *Herald*: Operations have been resumed at the Bullion mine, Grass Valley. Supt. G. Mainhart, who is an owner in the mine, has organized a new company.

Nevada City *Transcript*: The shaft of the Old Home, at the Kirkham place, Blue Tent district, is down 325 feet. At 350 feet another level will be started on the ledge and sinking continued. For 50 feet the shaft has carried the ledge, which is ochre, varying from 6 inches to 2 feet in thickness, having defined walls and carrying free gold. This is believed to be a continuation of the shoot which the Kirkhams worked fifteen years ago and which escaped them through a fault in the vein. There is a 5-stamp mill on the mine, and Supt. Logan expects to start next month and keep it running steadily.

Grass Valley *Union*: The Delhi at San Juan and the Live Oak at Columbia Hill are to resume operations.——The shaft of the Old Home mine at Nevada City is down 350 feet. Another level is to be started and sinking continued.

Orange.

There are coal indications at numerous places in the canyons back of Santa Ana, and coal has been mined in several veins, but nowhere on a large scale. The coal is lignite of rather inferior quality. It occurs at about the same geological horizon as the large deposits at the Chaney mine, near Elsinore, in Riverside county.

Placer.

The Morning Star M. Co., whose property is at Iowa Hill, have declared a $2.50 dividend, No. 100. It is the smallest paid for a long time. There are 100 men on the payroll.

Herald: San Francisco capitalists have bonded the copper property near Cooperstown. ——The Drummond mine, near Forest Hill, is to be started up again.——The Mayflower mine, near Forest Hill, has commenced hydraulicking.——The tunnel of the Alta mine, near Alta station, is now nearly 5000 feet long.

Grass Valley *Union*: The 5-stamp mill at the Red Stone, Blue Canyon, is running steadily.

Colfax *Sentinel*: Some fine looking quartz is being taken from the tunnel at the Azalea mine west of Blue Canyon.——The Van Avery quartz mine at Blue Canyon will resume operations soon.——The flood in Bear river caused by the recent rains has carried away the sluices, concentrator and other machinery of the Bear River Hydraulic Co., two and one-half miles north of Colfax.——Two years ago the United States Debris Commission granted fourteen permits to mine by the hydraulic process in Placer county. Only one of the mines, the Polar Star at Dutch Flat, has been able to run owing to scarcity of water. The recent storm will give nearly all of these mines a couple of months' run.

Riverside.

Old river channels are found in the hills southwest of the town of South Riverside, several hundred feet above the valley. Whether the gravels are gold-bearing or not has never been determined.

A nugget was discovered by some Mexicans who are working the placers on the desert near Virginia Dale. It was purchased by the San Bernardino Bank for $174. The district where the nugget was found should be a profitable field for the dry washer, for the hills are ribbed with gold-bearing veins.

San Bernardino.

(Special Correspondence).—The Gold Chief mine, six miles west of Manvel, and owned by R. Yound and others, is reported bonded. The property has considerable superficial development, and is an interesting one, geologically, being a large bed of quartzite, conglomeritic in part, and is gold-bearing. In many respects it resembles the Mountain Gold mines, sixty miles east of Victor in this county, on which at one time E. J. Baldwin of San Francisco built a 40-stamp mill.

Manvel, March 27th, '99.

C. A. Stilson and J. M. Hale are working the Gold Bronze mine at Vanderbilt, shipping their ore.

The Copper World mine, near Valley Wells, has a smelter in successful operation, producing 14,000 pounds of copper daily.

There are large bodies of low-grade copper ore in Mescal district, west of Ivanpah, and a few miles west of Vanderbilt copper ores are found in veins in granite.

Randsburg *Miner*: At Tecopah, near Resting Springs, Los Angeles parties are preparing to remodel and start the old smelter. This is a lead-silver camp. There are two big ledges with several claims on each.——Quinn & Dineen have their cyanide plant in operation in Pleasant canyon.

San Diego.

The Gold King mill, at the foot of Banner grade, is crushing ore from the Elevado mine, a mile southeast of Banner.

Years ago a 10-stamp mill was taken into the Oro Flamme canyon, east of Stonewall, and it is doubtful if it is ever removed. Some of the machinery was let down the steep hillside with ropes.

A prospector who went out into the Salton basin after a fruitless search of weeks made what he thought was a discovery of anthracite coal, and brought in all his pack animals could carry. It was black obsidian.

Yuma *Sun*: L. Auberry of San Diego has commenced erecting a 50-ton cyanide plant on a dump of tailings in the Picacho district, on the river a short distance below the old pumping plant. The dump is large enough to keep the plant running steadily for at least six months. The tailings are from the old Jaynes mines, which were worked years ago.

Shasta.

Redding *Searchlight*: The Sam Houston mine at Old Digging, adjoining the Texas, Con. was flooded by recent heavy rains and work had to be temporarily suspended.

Sierra.

Nevada *Transcript*: The Columbia Con. channel mine, owned by F. & W. E. Sharon and J. Harper, in what is known as the Henness Pass Ridge, will increase its operations. There is a 250-foot tunnel on the property, which will be extended to the channel. Waldemar Lindgren, United States Geologist, regards the Henness Pass as one of the largest intact gravel channels in California. It would have received the debris from the Sierra Buttes and other rich quartz mines.

Mountain Messenger: The North Fork Co. are in paying gravel. Thirty-five men are employed.——Men are at work on the Lucky Dog mine and the force will be increased.——At the Kenton mine on Kanaka creek, near Alleghany, twenty men are working. The mill is running also.——Lewis & Fessler own the El Dorado quartz mine near Alleghany. High-grade quartz is found in pockets.

Siskiyou.

There are in this county numerous good mines from which the loss in tailings is considerable. Only a few mills are equipped with concentrators; the cost of transportation and reduction is almost prohibitory. Chlorination or cyanide works are needed.

Yreka *Journal*: The Commodore Quartz M. Co., running a tunnel to tap the ledge at Barkhouse, Klamath river, expected to strike the ledge before now, and probably would but for its dipping further back into the hill at lower depth.——The Greenhorn Blue Gravel mine paid a dividend of 12½% recently from two weeks' work, net profit. The gravel yielded $250 a day, and double that amount Sundays, when all riffles are taken up. The mine is in charge of L. J. Wetzel.——The miners in the high and dry gulches have been doing work lately, securing sluice heads of water from the melting snow on the mountains, in addition to the rains. The hydraulic miners are rushing work with energy, having abundance of water to operate giants.——A. Steele, working the Ruwe claim at Cherry creek on shares, dug out a nugget recently weighing $34.

Yreka *Journal*: The Seattle Co., which purchased the Cape mine, on Greenhorn, from F. LeMay, received a quartz mill from San Francisco recently. There are several rich ledges on that creek and at other points around Yreka.——The Yreka M. Co. has been running their mill at Salmon river with a large force. The work at present is principally in developing.

Tulare.

Porterville *Enterprise*: J. McDonald, the principal owner of the Keystone mine, in Amador county, has bought the Minnie Ellen mine, eleven miles from Porterville, on the Halbert ranch, south of Deer creek, for $23,000, with an option for four months, during which time $3000 is to be paid Cook & Halbert; $1000 was paid down. Men will be put to work mining the rock, which will not be moved away unless the mine is taken. A stamp mill will be put in to test the rock.

Trinity.

Since the recent rains a large number of gravel mines are at work about Weaverville and the Trinity river is said to be lined in places with sluice boxes. On Nigger hill Mr. Lewmen has several miners at work.

Trinity *Journal*: The Indian Creek M. Co. is at work with a full crew.——Wm. Morris has struck pay dirt in his mine. The reservoir broke one day last week, sweeping flumes, etc., away. It will take some time to repair the damage.——La Grange Co., on Owen Gulch mountain, has expended a large amount of money in preparation and in securing water supply. Within two years it has driven a tunnel through Stuart's Fork mountain, a mile and a half, turning Stuart's Fork into Rush creek. A pipe line conducts the water for a good portion of twenty miles. The company owns or controls hundreds of acres of mineral land.

Tuolumne.

A vein of quartz rich in gold was discovered on the Barron ranch a mile and a half southwest of Soulsbyville in sinking a well. The soil and clay were nearly 25 feet deep.

The Columbia Tunnel & Exploration Co. have sunk several bore holes ranging from 100 to over 200 feet in depth. The site for the

proposed tunnel has not yet been determined upon.

The pump of the Bonanza mine in Sonora is unwatering the 1100 feet of incline and workings below the tunnel level.

R. M. Mein, E. A. Ogden and others have formed a company and bought the Mountain Belle, north of the Soulsby mine, which they propose to develop. The Soulsby mine is worked to a depth of 800 feet and is credited with the production of $6,000,000.

Independent: The mills of the Rawhide and App mines are running by water power.——The Crystalline group is preparing to start up with a large force of men.——J. Ferguson's 2-stamp mill in Sonora is running on ore from the pocket mines at Bald Moudtain.——A number of the large mines are using coal in place of wood.——The mill of the Bonanza mine is running.——The Alabama mine, near Jamestown, will start up soon. J. Gurrins is Supt.——C. L. Wilson of San Francisco has been inspecting the Belleview mine in the eastern belt with a view to purchase.

Union-Democrat: A gold chispa worth $35 was picked up on Washington street, Sonora, recently, and much of the metal in smaller nuggets was found, and many of the old dumps, washed clean by the rains, have proven little mountains of treasure.——Negotiations are under way for the purchase of the Bell mine, near Tuttletown. It has a shaft 400 feet and three crosscuts made, showing the body to be 50 feet wide.

COLORADO.

A Telluride, Colo., despatch says the Calumet & Hecla people have bought the Smuggler Union mines for $2,000,000.

BOULDER COUNTY.

At Puzzler over 100 men have been shovelling snow on the railroad that the mines might resume operations.

Development work on the St. George mine at Sunshine, begun last November, has continued.

The Ward Pyritic Smelter Company has contracted for the grading of ground for the new ore house addition to the smelter. This house will be 125 by 30 feet.

The Leviathan tunnel at Ward is now 200 feet deep.

The Dolly Varden at Sunset is getting out smelting and milling ore. The latest shipment showed a balance of $6 a ton after deducting hauling and the mill charges.

Denver *Post*: E. Thompson has received $75,000 from Springfield, Ohio, for the development of the Poor Woman mine at Sunset. A 1,000-foot shaft will be sunk.——The Evening Star at Sawmill hill, Ward district, has a streak which runs $30 per ton in gold.

Ward *Miner*: John Duncan has disposed of eighteen claims to the Columbia Mines Company.——The McDonald brothers of the Texas mine had twenty-five tons of ore run through the Giles mills this week.——A shipment of 4,800 pounds of ore made by leasers on the Ward-Rose, taken from the 200 east level, returned 7.20 ounces in gold.——M. Fishback has removed the steam hoist from the Chatham mine to the Honest John and sinking will be commenced.——The Newmarket Mining Company will run the 500 level several hundred feet west, and may sink the shaft 100 or 200 feet deeper the coming season.

Mining Record: The Boulder County mine at Caribou is working thirty-two men and there 1,500 tons of ore waiting for the Nederland mill to start up.——Preparations have been completed for the sinking of the Honest John shaft, at Ward, another 100 feet.——The Rip Van Dam tunnel is being driven, and the prospects for a strike are good.

CLEAR CREEK COUNTY.

The development of lodes within the townsite of Empire has commenced.——The discoveries made during the past season in mines that had lain idle for years will lead to increased prospecting of that class of mines when the winter passes. The success in the Silver Mountain and Empire City mines, with little labor and little capital, has created a demand for lease and bond of the producers of former times.——A find is reported in the breast of the lower adit of the Cleopatra mine, owned by P. Schnarr. Leasers have been extending the workings, and at a depth of 300 feet have almost solid ore, 3½ feet, and carrying $90 in gold per ton.

Silver *Standard*: It is reported that work on the Newhouse tunnel, at Idaho Springs, is to be resumed.——The new hoisting engine at the Corry City is acting satisfactorily and will be employed several days in handling the ore which has been taken out since the other engine was disabled. This is the second gasoline engine installed in this camp, the other being on the Frostburg.

Georgetown *Courier*: The Mt. McClellan M. Co. has sold its property, comprising the Stevens and Huckleberry groups—twenty-eight patented claims and six millsites—at the upper end of Clear creek, to C. K. Wolfe, H. Seigfried and J. H. Robson of Georgetown. The mines have produced over $2,000,000. The ores contain gold, silver and lead, and some of it is rich.

Gazette: The Atlantic mine at Empire will soon start up. The main shaft is 300 feet deep with levels every 75 feet, all in ore.——The Doric tunnel at Georgetown is now driven by two shifts.——Balotto & Co., have opened high-grade ore in the Smuggler, a mill returning 230 ounces of silver per ton.

EL PASO COUNTY.

It is currently reported at Colorado Springs that W. S. Stratton has sold his Independence mine to an English syndicate for a large sum, and that Mr. Stratton has gone to Europe.

Denver *Mining Record*: In cutting a station on the ninth level of the Portland at Cripple Creek a large flow of water was struck, which flooded the lower portion of the mine nearly to the eighth level.

Victor *Record*: The output of the Modoc mine at Altman for the month averages about a car daily, low grade.

FREMONT COUNTY.

Denver *Mining Record*: A one-half interest in the Copper King mine at Dawson, near Canyon City, was sold for $20,000 to T. C. Myers of Colorado Springs. Fifteen men will be put to work constructing a road to connect with the chute of 300 feet, this in turn connecting with the ore bins at the mine. Three shifts of six men each will drive the upper tunnel, and one eight-hour shift of two men will break ore.

GILPIN COUNTY.

Denver *Mining Record*: The Perigo mine, in the north end of the county and three miles from Phœnix, employs forty men, producing 150 tons per day. They have a 30-stamp mill. E. Stephenson of Boulder has contracted to sink a winze on the mine.——On Gamble gulch, in the Gold Dirt mine, lessees are cleaning out the drifts and shafts preparatory to putting on a large force. The working shaft is 500 feet down, and it is proposed to sink it to 1000 feet.——J. K. Brooks, one of the lessees on the Lone Star group at Perigo, is in Denver arranging for machinery for the Lone Star shaft. The ore at the bottom of the 175-foot shaft is very rich in gold, running up to thirty-seven ounces.

GUNNISON COUNTY.

Pitkin *Miner*: The ore houses of this district are filled with ore ready to be shipped and no way to get rid of it until the roads are opened again.

HINSDALE COUNTY.

Lake City *Times*: The Golden Wonder mine is a regular producer. It is stated that the ore shipped since the present leasing company took it has averaged $40. An 18-inch streak of $60 ore has recently been encountered in the drift in the bottom of the winze.

LAKE COUNTY.

The two pump men confined by the cave in the Bon Air shaft were rescued on the night of March 24th, after an imprisonment of thirteen days. A winze was sunk 200 feet to effect a rescue.

G. W. Cook, at the Garden City mine in California gulch, Leadville, promises to make of it the leading manganese producer. At present Mr. Cook is putting in place his new machinery, which includes a small pump to handle the water flow, as well as a large hoist. By the 1st of April both the Garden City and the Catalpa-Crescent will be hoisting the largest tonnage of manganese iron ever produced in their history and this tonnage will be kept up throughout the year in order to fill the big contracts made last month by Mr. Cook.

At the Moyer shaft of the Iron-Silver, Leadville, shipments have varied from 150 to 200 tons per day.

In this same vicinity the A. Y. & Minnie property, operated by lessees, owing to the bad roads, has been compelled to reduce its tonnage. The shipments from this combination have been averaging 1500 tons per month. In addition to shipping, about 350 tons of fine lead ore is the output.

Leadville *Miner*: Another strike of gold ore has been made on the Lime claim, on the south slope of Iron Hill, by lessees working with a windlass.——J. Beach has a lease on the north end of the Robert E. Lee mine, on Fryer Hill, and expects to find large bodies of iron ore. The mine was famous in earlier days for the masses of horn silver it produced.——On the Ground Hog mine, at Battle mountain, twenty-eight men are employed.

LARIMER COUNTY.

Denver *Mining Record*: A new strike of peacock copper ore has been made seven miles back of Fort Collins. The Empire mine in this district has a tunnel 130 feet on the vein and a shaft 80 feet. The formation is granite. The district is quite extensive, but little prospecting has been done. The ores are mostly sulphide copper, containing gold and silver.

ROUTT COUNTY.

A strike is reported to have been made in the tunnel of the Sunset claim on Yellow creek on the western slope of the continental divide near Steamboat Springs. It is a high-grade copper ore 20 inches in width.

In the Four Mile district the Rock Springs M. Co., Robert Nicholson & Co. and the Gold Valley M. Co. are making preparations to be ready to begin washing gravel by April 1st. The Gold Valley M. Co. will be able to run day and night. This company will employ fifty men.

The Hahn's Peak Placer Co., on the south side of the peak, near its base, will commence washing April 1st. Mgr. McFadden is in Denver. Forty men will be employed, with wages at 25 cents an hour.

SAN MIGUEL COUNTY.

Telluride *Journal*: A rich strike is reported from the Jim Corbett mine in Saw Pit. The ore was first encountered in a kind of cave, from the sides of which were taken some of the handsomest lime crystals and stalactites ever exhibited in Telluride.

SUMMIT COUNTY.

Denver *Mining Record*: The Swandyke camp is located near the head of Swan river, thirteen miles east of Breckenridge, and twenty miles west of south from Georgetown. The ores are sulphides in the main, though there is a belt of tellurium. The tellurium is calaverite, but it is upon the big sulphide veins that greatest dependence is placed. These veins are large, many 30 feet wide, and one has a width of 42 feet. They carry well-defined pay streaks of good grade. The belt runs between the heads of Montezuma and Hall valleys, which explains why it has remained undiscovered so long. The Pompa lode claim, which is only developed by a 15-foot hole, was recently sold for $1800. The ores carry gold, silver, copper and lead.

IDAHO.

Spokane *Chronicle*: The San Francisco group of claims in the Buffalo Hump country has been purchased by W. H. Wright of Spokane, representing an English company, for $100,000. The San Francisco group, one of the first locations, comprises the Baby Louise, Monte Carlo and San Francisco, three distinct ledges lying almost parallel with each other. Practically no work has ever been done.

Spokesman-Review: A strike is reported from the 16 to 1 at Wallace, in the Cœur d'Alenes, in a crosscut tunnel in 360 feet. Fifteen inches of clean galena were cut.

Hailey *Times*: Another strike—the second since the present management took the property—has been made in the Crœsus mine on the lowest level at a depth of 410 feet.

MONTANA.

Phillipsburg *Mail*: Smith & Kent, who own the Hidden Treasure mine on Lookout mountain, struck 18 inches of rich ore in their shaft a few days since at a depth of 160 feet, but were soon thereafter driven out by water. They will soon run a tunnel on the vein 900 feet, reaching a depth of 300 feet under the shaft.——Twenty-five bars of bullion were shipped from the Bimetallic mill Saturday. The shipments are now regular weekly. Forty men have been put on at the Bimetallic and Granite mines during the past ten days and it is the intention to increase the force of miners as soon as the work of repairing is sufficiently advanced. Seventy-five stamps are constantly dropping day and night at the Bimetallic mill at Clark.——Two bars of bullion were shipped Saturday from the Sweet Home mill, the result of a week's run on Cuno ore. Ten tons are crushed daily. The mill is now running day and night, both steam and water power being used.

Clancy *Miner*: Ten stamps of the Diamond Hill mill in Hassel district are being moved to the new gold mine at the head of Lump gulch, near Clancy, owned by D. W. Ross.——The Blue Rock is one of the group owned by the Gold Hill M. & M. Co., with headquarters at Great Falls, Mont., and are ten miles west of Clancy and twelve miles south of Helena. The formation at the mines is granite, their elevation 5500 feet. There are two porphyry dykes running the length of the property, a distance of 3000 feet. There are two quartz lodes in the porphyry, one about 3½ and the other 8 feet wide. The dykes vary from 40 to 100 feet in width and prospect throughout in gold.

NEVADA.

Pumping on the Comstock is expected to shortly resume. In all such new work there is always unavoidable delay in changes and additional arrangements in meeting hitherto untried conditions. The throat piece and improved inlet are now considered equal to requirements, and it is calculated that when the work of unwatering begins again the water can be lowered 200 feet before it becomes necessary to lower the pump.

Virginia City *Chronicle*: A Churchill county prospector, who has a 3-inch streak of quartz that pays by the hand-mortar, has utilized the windmill of a neighboring rancher for operating a 30-pound stamp, and pulverizes half a ton of ore in twelve hours, with wind for power.

Winnemucca *Silver State*: The Buck mine, four miles from Humboldt House, is reported bonded to Eastern men for $25,000.

Randsburg *Miner*: At Good Springs, forty-five miles north of Vanderbilt and fifteen miles east of the California line in Nevada, Prof. Shultz is putting in a leaching plant of twenty tons capacity, and working in the mines and mill about thirty men. This is a copper mine. The location was made years ago. The company are putting up buildings and are going to give it a thorough trial. There is plenty of water.

Territorial Enterprise: An agreement has been concluded with the Chollar and Potosi companies for the extension of the Zadig drift through the property of those companies to the Occidental Con. north line. This drift was run on the Brunswick lode on the Sutro tunnel level, 1000 feet south of the tunnel when work was suspended, and the face is 1100 feet north of the point where it will connect with the Occidental. The companies through whose ground the drift passes will contribute pro rata toward the work, with a prospect that ore may be discovered.

NEW MEXICO.

New Mexican: W. L. O'Kelly has purchased the Saddle mine, located between the Snake and Eighty-five mines of Hon. W. S. Hopewell.——Welch & McPherson have purchased the Flora Temple of Robin & Macy.——Negotiations are pending for the sale of the Eureka.——Hon. W. S. Hopewell has secured a lease and bond on the Eighty-five and has placed ten miners at work.——J. L. McLaughlin is the new owner of the Horn lease on the Sherman, and Bennet & Orchard have leased and bonded the El Dorado mine and work eight men.——The Cincinnati mine has put on a night shift of eleven men.——Teams and ore wagons are at a premium in the Hillsboro district.——A new hoisting plant has been placed on the Butler mine.——The force on the Grey Eagle has been increased to seven men.——The Placer Basin mine, owned by D. Essinger, is now yielding eight tons of $90 ore per day.——M. M. Freed has sold his twelve Cabello mountain copper claims to the Fidelity M. Co. of Salt Lake City.——J. M. Webster will resume work on his Lookout gold and silver mine, on Trujillo creek.

Rico *News-Sun*: The cyanide plant for the Old Abe mine, at White Oaks, is ready for operation. The main building is 165 feet in length, and other buildings cover the six tanks and boiler and engine room. Each of the tanks has 50 tons capacity and the entire works 300 tons per week. The tailings which have been accumulating and which are made by the 50-ton stamp mill will be treated. There are now about 10,000 tons of tailings, which average between $5 and $10 per ton. In the mine the shaft is down 1100 feet. The first station in the new shaft was cut at 800 feet, and at each succeeding 50 feet levels have been run.

Silver City *Enterprise*: At the Atlantic, working steadily, thirty men employed, the daily output of ore is ten tons. The drift is now 510 feet from shaft; a distance of 24 feet will make connection and open up another shoot of ore.

OREGON.

(Special Correspondence).—The Union-Companion mines at Cornucopia, owned by J. H. Searles & Co. of New York, have been partially closed down pending improvements to mine and mill. J. Arthur has contracted to put in a sluice box to save the black sands that contain the flour gold.

The Golconda mine at Sumpter, thirty miles from Baker City, has about completed its $100,000 bromo-chloride plant. Mr. Winters is Gen. Mgr.

Baker City, March 28th, '99.

The *Republican* of Baker City publishes a list of mines near Baker City and says the mills have a total of 373 stamps and the mines give employment of 1113 men. The list comprises eighty-five mines.——It is claimed that the Vaughn copper mine on the Oregon side of Seven Devils is 130 feet wide.

SOUTH DAKOTA.

The Homestake Company at Lead City are building an experimental cyanide plant.

Custer *Chronicle*: The Gold Coin mines, eight miles west of Custer, have been transferred to the Vigilante Mining and Milling Co., for $99,000.——A new shaft is to be sunk on the Grand Junction mine seven miles northwest of Custer. The mine is a very large one but has never been properly managed.

Times-Pioneer: Criley & Bell who have the lease on the Wildcat, near Deadwood, owned by Aaron Dunn and associates, in Spruce gulch, have found a good sized-body of ore in a tunnel they were driving. The Wild Cat joins the Belle Eldridge on the lower side, and runs up to the Champion.——Isaac Downing and partners, who have the lease on the Belle Eldridge, are taking out ore and hauling it to the smelter.——The Champion, owned by the Highland Chief Mining Company, has resumed operations. This work is under the supervision of J. C. Randall.

UTAH.

Tintic *Miner*: Operations will be resumed at the Bullion-Beck mill. Water will be obtained from Mammoth.

Salt Lake *Tribune*: A force of men has been sent out to renew work on the New Moon in Skull valley. They will resume work by crosscutting in the vein. The New Moon is a promising cyanide property. A mill will propably be built during the summer.——The Diamond Con. M. Co.'s property on Treasure Hill near Silver City, Tintic, reports the new shaft down 65 feet and thoroughly timbered. Bunches of copper ore have been found in sinking assaying as high as 23.4%.——A rich strike is reported from the May Day mine at Tintic.——Ore carrying lead values has been struck in the Yankee mine situated near the May Day and the Humbug at Eureka.——President Newhouse of the Highland Boy Co. says that the Highland Boy smelter, now in course of construction near Murray, will be running and handling ore by June 1st. The tramway from the mine is finished and will soon be hauling the ore from Bingham down to the smelter.——The Mountain View mine near the Humbug at Eureka, has reported breaking into a good ore body.——It is said that high-grade ore had been struck in the Northern Light, Eureka, in the south drift.——The Tusquella mine on the West Dip, Camp Floyd district, has broken through the shale in the new shaft and has ore at 125 feet.——The Joe Bowers Extension Co. require sinking pumps with a capacity of sinking to a depth of 1000 feet on their property at Tintic.

Park *Record*: A few men have been put on at the Ontario.——Seventy men are working at the Daly-West. The mill is to be started next week.——The Webber & Kearns concentrator at Park City is being repaired. It will require a month to finish it. Some new machinery is to be added.——It has been found necessary to make many changes in the new King mill. It will probably be five weeks before the machinery will be put in motion.——The shaft at the Silver King is down 1300 feet.

After sinking a sump and cutting a station at this level, a drift will be run to cut the ore body.——Plans for the new Anchor mill will be out next week.——The Superior M. Co. has let a contract to R. Smith to sink an incline of 100 feet on that property.

WASHINGTON.

A 20-ton concentrating plant is en route to the Crystal Butte mine on Meyers creek on the Colville reservation. About April 1st Mgr. Thomas will employ twenty-five men if he can find them. The lead varies in width from 10 inches to 2 feet.

The office of the new Republic Co. will remain in Spokane.

A bed of lignite has been found in Asotin county. The deposit has been traced up the Snake river from Mallery Ridge as far as Elbow canyon, and crops out in several places along the river in Wallace county, Oregon.

Coeur d'Alene *Press*: The Palmer Mountain G. M. & T. Co. of Spokane owns forty-three claims in Palmer Mountain district, west of Republic, with a crosscut tunnel now in 1700 feet with nine veins cut. The depth at the present face is 900 feet. No drifting has been done.——The El Dorado has a 60-foot tunnel on ore going 20% to 25% copper. J. P. Dexter is working it.——On the Mammoth, a Whisky Hill property, a crosscut is running to tap the vein 500 feet deep.——The Golden Zone has 2000 feet of tunnels, all in ore. A concentrator is now being erected.——The Okanogan Free Gold Mines, Ltd., of Rossland has 280 feet of tunnels, numerous open cuts and shallow holes, and is erecting a mill, concentrator and cyanide plant. The company will mine an average of 200 feet deep before sinking will be necessary.——At Weheville the J. G. Blaine shaft is down 60 feet and the bottom in ore. A contract for 200 feet is in progress.

At Spokane last week fourteen more new mining corporations were launched.

Spokane *Chronicle*: At a recent meeting of the new Republic Co. it was announced that it is proposed to develop the Republic by a double-compartment shaft to be sunk 1000 feet and the capacity of the cyanide mill is to be more than doubled.——G. W. Runnels has opened a ledge of black oxide of copper on the Iconoclast claim on Tollman mountain, near Keller.——Supt. R. C. Vandeford of the Umatilla, near Keller, which is being developed by Finch & Campbell of Spokane, reports the tunnel in 335 feet. He expects to cut the ledge soon at a vertical depth of over 200 feet.——The men working the Teddie claim, about a mile and a half east of Keller, have cut the ledge at a depth of 50 feet with a crosscut tunnel 92 feet and exposed a large body of low-grade sulphide ore. The ledge is 25 feet between walls. The mine is owned by a Spokane company, headed by T. S. Griffith.

Spokesman-Review: The Crystal Butte, in the northwest corner of the Colville reservation, has made another strike. The winze is down 140 feet, with a pay streak 30 inches wide and an average assay across the ledge in the bottom of the winze of $162 per ton in gold. Free gold shows plainly in much of the ore.——In the Review claim a strike of free-milling ore has been made, and R. Allison, one of the owners of the claim, is going to arrange for the erection of a 10-stamp mill.——The Jersey Lightning Co. has let a contract for 25 feet of shaft on that property. The company will put a stamp mill on the claim if the values hold out as the shaft goes down.——The Ben Wharton Co. is working four men and has struck the vein at a depth of 50 feet in the shaft which was sunk to catch the vein on its dip.——Supt. Hoffman of the Scotia mine on Toulou mountain, near Roseburg, has received samples of ore from the bottom of the shaft which is being sunk under contract. The ore is chalcopyrite. The shaft is down 63 feet.——The ore in the Princess Maud at Republic has undergone a change from the friable sugar quartz to a hard, dense variety, though the value has improved somewhat, and the vein maintains its width, about 5 feet.——The Lexington G. M. Co. has been organized to develop the Lexington claim on the west fork of the San Poil, near the mouth of Gold creek. The ledge lies between slate and porphyry, and shows a width of 40 feet on the surface, a mixture of quartz and porphyry. About 6 feet below the surface the material gave assay values of $6.40. At 32 feet the values have risen to $18.60 per ton in gold.——The sale of a half interest in the Santa Fe and Kodak claims, north of the Rogers' Bar trail and two miles east of the San Poil, in the south half of the Colville reservation, by C. W. Wagner, to Spokane men is reported. The price paid is not made public. A contract was let to C. W. Wagner and J. Payne to sink a 50-foot shaft on the Santa Fe. Mr. Wagner states that this claim shows a ledge 10 feet in width that assays from the surface and from open cuts from $6 to $20 per ton.——News of good developments in the free-milling ledges of the Myers Creek district, in the northwest corner of the Colville reservation, is received.

WYOMING.

(Special Correspondence).—The idea seems to have become general that Wyoming was almost exclusively a pastoral State. This is not so, however, as the present year will demonstate. In western Wyoming are gold mines of undoubted value, and some also in the extreme eastern edge of the State in the Black Hills, where not only gold, but lead, silver, tin and iron are found. In the Hartville region are large iron mines, at Rawhide Buttes, copper, and also near Grand Encampment, in the southern part of the State. There are immense coal deposits in several portions of the State, and we have dry lakes in the beds of which are valuable deposits of soda, borax, etc., and gypsum beds extending for miles, oil wells, and much else, besides building stones, clays and beds of sand, all of which have commercial value.

Laramie City, March 20th, '99.

Salt Lake *Tribune*: The Union Pacific Company has bought the Kindt coal mine, on the road between Fort Steele and Saratoga, which is taken to indicate the probable building of the line from Dillon, Colo., to Fort Steele.

FOREIGN.

AUSTRALIA.

The Wallaroo mine, it is said, was discovered by means of the green copper carbonate thrown out in a small mound by a burrowing animal. The mine was developed by private capital and the first four or five years the balance sheet showed a debit of about $400,000. Now it is one of the most extensive and valuable properties in South Australia. The ore carries about 13% copper.

BRITISH COLUMBIA.

The Trail smelter will soon be supplied with lime from the newly discovered quarry, a few miles from Nakusp.

Spokesman-Review: The double compartment shaft on the North Star, at Fort Steele, is down 215 feet. A station has been started at the 200-foot level to crosscut the lead.——The tunnel on the Stemwinder on North Star hill is in 95 feet.——On Tracy creek work has been resumed on the Minnie and Tiger claims by the Fort Steele Development Company. The claims show galena from the grass roots in a contact vein.——It is reported at Fort Steele that the Moyie and Queen of the Hills mines at Moyie have been sold to an English syndicate.

The Kootenaian: The Vulture mine in the Slocan has made another strike, 2 feet of solid galena ore with 1½ feet of carbonates in the face of the tunnel, making a continuous vein the length of the tunnel which is 180 feet; the ore shows on the surface for 1,000 feet.

Rossland *Miner*: J. Moran who recently sold the Kamloops mine, Camp McKinney, to Rossland parties, has been offered $15,000 for his one-fourth interest in the Okanogan claim, situated on the eastern end of the Cariboo group.——The vertical shaft on the Minnehaha at Camp McKinney has reached the 200 level, and the crosscut commenced. It is expected the vein will be cut in 30 feet when stoping will be commenced at the 100 and 200-foot levels. The mill will probably be in operation by August 1.——An order has been placed in Montreal for a 15-drill compressor for the Cariboo mine at Camp McKinney to be installed and in operation within sixty days. Recent development has caused the company to arrange for ten more stamps for the Cariboo mill.

Victoria *Times*: The rich strike recently reported from the Three W's mine was on Granite creek, ten miles east of Alberni canal. The vein has been stripped 40 feet and is 2 feet wide. The quartz is honeycombed and shows considerable free gold. About 200 feet distant from this strike another excavation has been made, apparently on the same vein.——The Golden Eagle mine, at Alberni, has been closed down owing to frequent snowslides.——Additional men are at work on the True Blue, four miles from Kalso, under bond to the Hall Mines, Ltd., of Nelson.

MEXICO.

The volcano of Colima, in the State of Jalisco, is again active. The inhabitants are leaving the vicinity.

Two Republics: G. Hopkins, formerly a mine manager in the Organ mountains of New Mexico, has purchased from E. Baird the Cushinbery copper property, situated on the east slope of the San Andreas, south of Mimbrillo canyon. Mr. Hopkins will at once reopen the mine.

El Paso *Times*: E. R. Jewett has discovered in the Sierra Madre country silver-copper ore which assays ninety ounces silver and 15% copper to the ton. The prospect is sixty miles from Casas Grandes and is the first discovered in that vicinity, although there are a number twenty miles distant. As it is accessible, it is a desirable locality, and prospectors are flocking there.——Two new strikes have been made in the San Blas mining district, on the Sierra Madre Railroad, of copper ore which assays 20% to the ton and some silver.

SPAIN.

The *Revista Minera* of February 24 furnishes details of the Spanish mineral statistics for 1898. The silver ingots obtained in Spain last year amounted to 114,020 tons. The production of lead was as follows:

	Tons.
Crude lead exported	178,885
Manufactured lead exported	979
Lead in ores exported	4,400
Lead consumed in Spain	8,500
Total	193,764

Assuming that the ores yield on an average 55% of metal, this total represents a production of 352,000 tons of lead ore. The Government mine, Arrayanes, produced 18,961 tons of lead ore. The Spanish production of mercury last year was as follows:

	Flasks.
Almaden	46,211
El Porvenir (Mieres)	1,450
La Union Asturiana (Mieres)	450
La Soterrana (Pola de Lena)	71
Other mines in Asturias and Granada	540
Total	48,722

THE PHILIPPINES.

E. M. Hand, a Montana mining expert and assayer, who was sent to the Philippines by a Holland company that owns a concession of mineral land ten miles square, fifty-six miles inland from Gorontalo, writes from Finando: "Out of thirty assays so far I have only found a trace of gold and they were from places that were supposed to go $20 or over. I do my own prospecting, but always have fifteen or twenty natives with me. I am a miner, carpenter, blacksmith and assayer. It would not be a bad job if it wasn't for the heat. That is perfectly damnable, but the nights are cool, so one rests well. It is always shady in the jungle but very sultry, as there is never a breath of air."

Industrial Notes.

—A Ballard, Wash., shingle mill in '98 cut 322,000,000 shingles.

—Arizon's copper production in '98 was worth over $19,000,000.

—Jefferson Co., Montana, has sold its 4½% bonds at 1% premium.

—Leadville, Colo., will buy the present water plant for $350,000.

—In '98 San Francisco exported $40,000,000 worth of general products.

—Spokane, Wash., is boycotting Chinese labor and Chinese-made goods.

—Seattle, Wash., last week let a $38,000 sewer contract to F. McLellan.

—Wages in Washington logging camps this season are from $1.50 to $3 per day.

—A $350,000 beet sugar factory is to be built in Spokane, Wash., by D. C. Corbin.

—During '98 Denver's manufactured products aggregated in value $25,600,000.

—The O. R. & N. Co. will build from Moscow, Idaho, to the Clearwater country.

—Drought in New South Wales has in the last two years destroyed 8,000,000 sheep.

—A paper mill "to cost $350,000 and employ 400 hands" is to be built at Floriston, Cal.

—Oranges and potatoes were the same price at Sacramento, Cal., last week—25 cents per dozen.

—Sacramento, Cal., is about to bond itself for $400,000 for sewerage, street improvement and water works.

—The Santa Fe road has ordered 2000 freight cars in anticipation of a big wheat crop in the San Joaquin, Cal., valley.

—The new Alaska code of criminal procedure, in effect July 1st, '99, will provide to the U. S. treasury an annual revenue of $500,000.

—Another big railroad war has started, and the Pacific coast conventions next summer may cause its continuance through the year.

—A Seattle, Wash., transportation combine, contrary to established usage, has cut in two passenger and freight rates to Dawson City.

—Through the sale of Mrs. Jane Stanford's Central Pacific R. R. stock the Stanford, Cal., University will receive nearly $2,000,000 more.

—Wells-Fargo Express Co. has absorbed and ousted some of its competitors, and now nearly controls New Mexican and Colorado business.

—Since Aug. 1st, '98, 40,000 tons of coal have been sent to Manilla, Philippine islands, from this country, mostly from the Atlantic side via Suez canal.

—San Francisco's new city hall is "completed." It was begun just twenty-nine years ago. It was to cost $1,500,000. To January 1st, '99, it has cost $5,723,987.

—Moran Bros., Seattle, Wash., shipbuilders, have sued the North American T. & T. Co. for $37,642, balance due on the construction of Yukon river steamers.

—The story of Russia's building a ship canal to connect the Black and Baltic seas is a diaphanous fake, started by a space writer on a Sunday daily and extensively copied.

—A. Godbe of Ensenada, Lower California, Mgr. of the mines fifty miles south of Ensenada, is reported to have contracted with the Japanese Government to deliver 500,000 tons of iron ore.

—Despite a lack of recent rain southern California will have a prosperous season, all its varied industries being in good shape. That section of California shows great increase in wealth, population and industrial development.

—In San Francisco Claus Spreckels and associates have organized the Independent Electric Light & Power Co., capital $10,000,000, to supply San Francisco residents with electric light and power at considerably less cost than at present.

—The old monitor Camanche, which has been bought from the Government, is to be converted into a freight ferry boat to be run on San Francisco bay. Her antique engines will be replaced with new machinery and she will be remodeled at a cost of $50,000.

—The pole line of the Blue Lakes, Cal., power plant is completed from Stockton to Mokelumne Hill. The power will equal 50,000 H. P. Danger signals have been posted along the poles to the power house warning persons against coming in contact with the wires under penalty of their lives.

—There are now eight regular lines of steamers plying between the ports of the United States and British Columbia on one side of the Pacific ocean and China and Japan on the other side, besides two lines running to Australia and New Zealand. Several of these lines also touch at Honolulu.

—The Utah & Pacific road is building an extension from Milford in Utah in a southwesterly direction to a point in Nevada. From there a branch line will be built to Pioche. The line will be operated by the Utah & Pacific people, but they will have a traffic exchange agreement with the Oregon Short Line at Milford.

—The Clear Lake, Cal., Power Co. expects that the Cache creek of Lake county will furnish water power to generate electricity for illuminating and power purposes, to be conducted to Santa Rosa, Calistoga, St. Helena, Napa, Vallejo, Petaluma and Benicia. A diverting dam is projected to guide the water into a flume 4x8 feet, following the contour of the mountains for five miles, the flume having a fall of 5 feet to the mile, and having an elevation of 262 feet above the creek bed at the terminus of the flume. The water is to be carried in three 40-inch pipes, 950 feet to turbines in the power house. These turbines are to be on the same shafts with the dynamos. From the power house a pole line conveying six wires, carrying 40,000 volts, is to be constructed to Calistoga.

—At the port of Kobe, Japan, the imports and exports together for '98 were valued at $99,126,000, against $81,074,500 for '97. The imports represented $69,066,500 in '98 and $55,370,500 in '97. The exports for the two years were $30,059,500 and $25,704,000, respectively. The commerce of Kobe during '98 was almost $3,500,000 in excess of that of Yokohama, thus making Kobe the leading commercial port of Japan.

—On the Siberian railroad work is conducted directly by the Government without the mediation of contractors. Laborers are chiefly from European Russia, reinforced by natives of Siberia and gangs of convicts. The mechanics are chiefly Italians, Belgians and Poles; track-laying is done by the railroad batallions of the army; in Eastern Siberia and Manchuria Chinese coolies are employed. About 10,000 men are at work on the line west of Lake Baikal, on which the track is nearly all laid, and 6000 east of it. The engineers are all Russians. As far as possible materials are obtained from the country on the line. The road is being cheaply constructed, with steep grades and sharp curves, and does not admit of high speed. The fastest train at present—once every two weeks—runs seventeen and one-half miles an hour. The line east of the lake to the Amoor valley, 688 miles, is called the Transbaikal railroad. Work has been prosecuted on it since 1895, and it is to be completed this year, at least at far as the river Onon, 563 miles from Lake Baikal, where the Chinese Eastern railroad begins. The construction of a railroad down the Amoor valley, 1332 miles, which was the plan before the right to build through Manchuria had been secured, seems definitely abandoned. The whole length of the line from Cheljabinsk, near the European border, through Manchuria, to Vladivostock, including a circuit of Lake Baikal, will be 4120 miles; Cheljabinsk is 2225 miles from the line between Russia and Germany. The line as far as Irkutsk is 2022 miles long. Vladivostok, the Pacific terminus, is credited with 15,000 permanent inhabitants.

—The San Francisco & San Joaquin Railway Co. has transferred to the Santa Fe the terminal site at Spear and Harrison Sts., San Francisco, and the property adjoining. Taking the revenue stamps attached to the deed as a basis for the price of the property, $378,000 was paid by the railway for its terminus in San Francisco. Governor Gage of California has signed the so-called Santa Fe Consolidation bill. This is the measure introduced at the instance of the Santa Fe people for the purpose of permitting, as its advocates claimed, that corporation to operate its system as a whole, instead of being compelled to do so through the medium of three or four different corporations. It was asserted that, unless the existing laws were amended, it would be impossible to purchase the line from Mojave, Cal., to the Colorado river, necessary to complete the system. The leading feature of the Act is made clear by the following excerpt: "Any railroad corporation owning any railroad in this State may sell, convey and transfer its property and franchises, or any part thereof, to any other railroad corporation, whether organized under the laws of this State or of any other State or Territory, or under any Act of Congress; and any such railroad corporation receiving such conveyance may hold and operate extensions and branches thereof and do any other business in connection therewith, as fully and effectually to all intents and purposes as if such corporation were organized under the laws of this State." The bill was opposed on the ground that it would permit the consolidation of the Central and Southern Pacific Railroads.

Recent Mining Incorporations.

Nut Pine G. & S. M. Co.; capital stock, $100,000; subscribed $50; E. and G. H. Lent, W. F. Humphrey, C. O. and R. G. Hooker.

Dirigo Con. M. Co., San Francisco, Cal.; capital stock, $1,000,000; subscribed $150,020; W. W. Great, C. W. Cross, G. R. and L. F. Tuttle, H. Newburg.

Big Oak Flat M. & D. Co., Oakland, Cal.; capital stock, $100,000; D. R. Shafer, J. H. Williams, Big Oak Flat; C. H. Wever, H. H. Castle, Alameda; H. S. Aldrich, Oakland.

Green Jumper G. M. & D. Co., Sonora, Cal.; capital stock, $52,500; J. T. Ryan, E. J. Landers, F. Corbin, J. W. Purdy, Sonora; W. S. Risley, Alameda.

Bown M. Co. (amended articles), San Francisco, Cal.; capital stock, $1,000,000; subscribed $50; J. M. Wright, H. C. Park, San Francisco; W. J. Rule, P. Rowe, Tuttletown; W. Chartron, E. J. Dubois, J. Monthiers, Paris, France.

Commercial Paragraphs.

THE Marion Steam Shovel Co., Marion, Ohio, has sold within the past two weeks twelve steam shovels for shipment to Russia.

THE Hassell Iron Works Co. of Colorado Springs, Colo., whose present specialty is the automatic horse whim, recently made shipments of same to Buenavista, Colo., and Gila Bend, Ariz.

THE Jeanesville Iron Works Co., Jeanesville, Pa., last week received an order from one of the large coal companies near Scranton for four 10x6x12 inch boiler feeds; two 22x10x36 inch wood-lined duplex mine pumps; one 20 and 38x16x48 inch compound condensing duplex mine pump; one 16–24 and 40x16x46 inch triple expansion duplex mine pump, including two large condensers for the two latter pumps.

Personal.

GEO. H. EVANS is at present in South America.

HENNEN JENNINGS has returned to London from San Francisco.

H. E. PICKETT has returned to Placerville, Cal., from the East.

W. F. GORE now has charge of the dredge at Big Bar, Fraser river, B. C.

R. C. CHAMBERS, Supt. Ontario mine, Park City, Utah, is in Butte City, Montana.

W. H. PAUL, of Denver, is consulting engineer for the Bassic mine, Silver Cliff, Colo.

H. ZADIG of San Francisco has returned from a visit to the Occidental mine at Virginia City, Nevada.

SENATOR DORSEY of Colorado, who has mining interests at Pichaco, Cal., has gone to New York City.

V. T. MCGILLICUDDY, formerly dean State School of Mines, Rapid City, South Dakota, is at Olympia, Wash.

M. H. DEYOUNG of San Francisco is appointed California's official representative at the Paris Exposition.

JOHN ROSS, JR., Supt. Wildman-Mahoney mine, Sutter Creek, Amador Co., is temporarily sojourning in Oregon.

SIMON GUGGENHEIM, Gen'l Mgr. Philada Smelting & Refining Co., says the Guggenheim smelters will not enter the trust.

T. A. RICKARD, State Geologist of Colorado, was this week reappointed for his third term, a deserved recognition of efficient service.

E. G. DENNISTON, proprietor of the Denniston San Francisco Plating Works, has returned from a business visit to Los Angeles, Cal.

W. G. SCOTT, of Shasta Co., Cal., suggests the formation of an organization to be known as "The Pacific Coast Society of Mine Superintendents."

E. H. BENJAMIN, secretary California State Miners' Association, was in Los Angeles this week, extending the membership of that organization.

JOSHUA D. HOSKING of the Kearsarge mine of the Osceola Con. to-day succeeds Graham Pope as Gen. Mgr. and Supt. of the Franklin mines at Houghton, Mich.

P. P. BUSH of Denver, Colo., western representative of the Canton Steel Co., is making a trip through the Northwest. He was in Butte, Mont., March 25th.

S. C. IRVING, President Paraffine Paint Co., of San Francisco, has gone to Washington, D. C., in the interest of the California Manufacturers' and Producers' Association.

H. G. MURRAY, who for several years has been foreman of the Gwin mine, has resigned his position to accept the superintendency of the Lightner mine at Angels, Calaveras Co., Cal.

LOUIS JANIN, SR., E. M., AND J. H. MEANS, E. M., of San Francisco, Cal., have gone to British Columbia in connection with the litigation involving the Iron Mask mine and North Star.

B. I. WHEELER of New York is in San Francisco and is prominently mentioned in connection with the presidency of the University of California, made vacant by the recent resignation of Martin Kellogg.

CHAS. S. DODGE has bought the Washington Gulch, Montana, placer plant, formerly owned by W. M. Johnston & Co.. This property was illustrated and described in detail in the issue of Feb. 5th, '98.

MR. E. I. PARSONS, for so many years constructing engineer for the Hallidie Ropeway and the California Wire Works, takes a position on the 1st inst. with the John A. Roebling's Sons Co., 25-27 Fremont street, San Francisco.

MARCUS DALY of Montana is in New York City, where he is locally credited with intention to turn the management of the Anaconda over to the Standard Oil Co., though it would seem that if any one was so empowered, J. B. Haggin would be the man.

E. W. NASH, Sec'y Omaha & Grant Smelting Co., has been elected president of the smelter trust with headquarters at Omaha. Mr. Nash is credited with the assertion that the capitalization of the company will be $100,000,000, and that the trust includes every smelter in the country except Guggenheim's of Pueblo.

THOS. B. BURNS, cashier San Francisco Subtreasury has returned from Philadelphia, where he attended the Assay Commission, being the first Sub-treasury employe thus appointed. The Assay Commission this year recommended that the standard weights be annually in December compared with those of the Bureau of Weights and Measures.

CHARLES R. WORES of the Tucson, Arizona, sampling works says that hundreds of assays are being made to-day where there was comparatively no work a year ago. Mr. Wores attributes this to the general activity in his section and to the price of assaying at the Arizona University, as prospectors give the local assayers the preference with prices the same.

JNO. T. GRAHAM of Denver, Colo., is authority for the statement that the first step made by the new smelter trust and combine will be to advance the price of silver 10%. He says the trust's operations will be beneficial instead of oppressive, and that all who entered into the combine signed a contract agreeing not to raise the price of treatment of ore for ten years.

AT the first meeting of the newly elected board of directors of the Manufacturers' and Producers' Association, in San Francisco last Monday, the old board of officers was elected, as follows: President, A. Sbarboro; first vice-president, James W. Kerr; second vice-president, Frank L. Brown; third vice-president, J. P. Currier; treasurer, A. Sbarboro; secretary, Lewis R. Mead.

SCOTT MCDONALD of Spokane, Wash., is in San Francisco for his health. He held a big interest in the Payne mine in the Slocan, B. C., till last week. The mine is sold to Canadians, who will move the office from Anaconda, Montana, to Montreal. W. L. Hogue of Anaconda is to be president. The shipments from the Payne mine from Jan. 1st, '99, to March 14th, '99 (the day of sale), aggregated 2388 tons, which netted $52 per ton after deducting duty and all charges for freight and treatment.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey, Strong & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING MARCH 21, 1899.

621,772.—LUGGAGE CARRIER—A. L. Bancroft, Walnut Creek, Cal.
621,773.—FRUIT PRESS—L. Blatz, La Miranda, Cal.
621,445.—LAWN MOWER—Campbell & Woodworth, Dayton, Wash.
621,774.—PRESERVING WOOD—C. S. Chamberlain, Oakland, Cal.
621,636.—TOILET PAPER CASE—Davis & Cornelius, Turner, Or.
621,775.—FEED WATER HEATER—G. F. Day, S. F.
621,653.—BRAKE ADJUSTER—Gilman, Norton & Brown, Tacoma, Wash.
621,524.—MITER BOX—W. H. Gordon, Portland, Or.
621,566.—WATER GATES—J. H. Hendy, S. F.
621,768.—FILTER—T. W. Hill, Los Angeles, Cal.

NOTE.—Plain and Certified Copies of U. S. and Foreign patents obtained by Dewey, Strong&Co., by mail or telegraphic order. American and Foreign patents secured, and general patent business transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

ANTI-FRICTIONAL ATTACHMENT FOR WATER AND OTHER GATES.—J. H. Hendy, San Francisco, Cal. No. 621,566. Dated March 21, 1899. This invention relates to an attachment for water and other gates, and is especially designed to relieve the friction of the flange of the turnable nut by which the gate actuating screw is reciprocated in one direction or the other in order to open or close the gate transversely of the passage which it controls. It consists essentially of a gate movable transversely across the water pipe or other passage which it controls, a screw-threaded nonturnable stem connected therewith, a nut through which the threaded portion of the stem passes and a hand-wheel by which the nut is turnable. This nut has an outwardly projecting annular flange at the bottom and a chambered cap within which the flange is turnable. Grooves are made in the opposing faces of the flange and the interior of the chamber and balls are fitted in these grooves to make an easily movable joint so that the nut can be readily turned to advance the gate in either direction. The faces of the interior of the chamber may have removable disks fitted in them with the grooves formed in these disks so that they can easily be replaced in case of wear.

FEED WATER HEATER AND PURIFIER.—Geo. F. Day, San Francisco, Cal. No. 621,775. Dated March 21, 1899. This invention relates to improvements in apparatus for heating and purifying the water which is to be supplied to boilers for steam purposes. It consists essentially of an outer shell or casing having transverse diaphragms separating it into independent vertically disposed chambers, one of which is a clear water chamber, an inlet passage opens into the lower part of the uppermost chamber to admit exhaust steam and an outlet therefor from the top of the chamber, a relief pipe exterior to the chamber connects the clear water chamber with the lowermost chamber. Horizontally disposed trays are suspended in the uppermost chamber to form alternate passages for the steam and water upon opposite sides. The pipe connecting the upper heating chamber with the lower sediment chamber is formed with plugs in line with the pipe and with its connections with the chambers so that it may be easily cleaned and inspected. A rising and falling float within the clear water chamber has a hollow arm and a hollow shaft, the ends of which extend through stuffing-boxes to the exterior of the chamber so that any leakage into the float will be discharged therethrough. A crank arm is also fixed to the shaft and is connected with a valve which controls the water inlet in unison with the rising and falling of the float so as to regulate the supply of water to the heating chamber. An automatic sediment discharge device is connected with the sediment chamber comprising a steam trap and a valve which is opened periodically by the action of water supplied to the trap so that steam is admitted to operate upon a piston and operate the discharge valve of the sediment chamber.

Mining Companies, Attention.
Capitalist wants to open general store in mining camp, where company is willing to receive orders against the miners' pay. Will pay for privilege. State number of men employed.
Address S. S., this office.

A MINING DETECTIVE.—"Confidential," operating in California, Arizona and Colorado. I am prepared to investigate as to habits of employes on duty (also off duty) in mine and mill, particularly the art of stealing gold specimens, amalgam, ores, etc., from mining companies. Best of references. Reasonable terms. Address "Confidential," M. & S. P. Office, San Francisco, Cal.

POSITION WANTED by experienced cyanide man in charge of a mill. Technical graduate. Good chemist and assayer. Speaks Spanish. Salary moderate. Address K. C. N., Mining and Scientific Press.

WANTED--AN ASSAY BALANCE
IN GOOD CONDITION.
State price and make. Address H. A. C., this office.

MINING ENGINEER WANTS POSITION. Thorough chemist and assayer: practical experience of stamp milling, chlorination and cyanide processes. Three years' experience examining and reporting on mines. Familiar with Mother Lode. Any capacity; moderate salary. Address "B. L." this office.

WANTED—SITUATION BY A PRACTICAL MILLMAN AND ASSAYER.
Would go anywhere. Best of reference. Address F. B., care of Mining and Scientific Press.

WANTED---A PRACTICAL ASSAYER.
GOLD HILL QUARTZ MINING CO.,
Gold Hill,.....Oregon.

WANTED.
Capital to Handle Extensive Gold Mines.
JAMES ARTHUR, Cornucopia, Oregon.

SITUATION WANTED.
Have had over twenty years' of practical experience in mining, milling, and erecting machinery; thoroughly up to date in working all kinds of ore by the latest methods; can handle men to the very best possible advantage. Will accept of a position to manage a mine, mill, or erect any kind of mining machinery. The very best of testimonials furnished as to abilities, integrity, etc. Address Experience, care Mining and Scientific Press.

Wanted to Bond a Gold Mine
IN CALIFORNIA OR ARIZONA, on which parties will do development work.
Address P., 347 Wilcox Building, Los Angeles, Cal.

Have Purchasers for Good Copper and Gold Mines
IN THIS STATE, ARIZONA AND MEXICO. Reliable reports required and options later, if approved of. RUSSELL & POOLEY, 349 Wilcox Building, Los Angeles, Cal.

DIAMOND DRILL FOR SALE.
OR CAN BE HIRED, TOGETHER WITH EXPERT TO OPERATE IT.
Apply to J. A. MURRAY, care of Risdon Iron Works, San Francisco.

..CRIPPLE : CREEK..
FOR SALE—CYANIDE PLANT,
100 tons daily capacity; in first-class condition to handle Cripple Creek ores.
Plant in full running order, with all latest improvements. Address JOHN S. MACBETH, Equitable Building, Denver, Colorado.

The State Ore Sampling Co.
DENVER, COLO.
We buy Gold, Silver, Lead, Copper, Bismuth, Uranium, Wolfram, Cobalt and Antimony Ores. With modern mills and machinery our facilities for sampling ores are the best.
Our long experience in the market enables us to obtain the highest prices for all marketable ores. Write for our "Reference Book." Send analysis of your ore for prices and information.

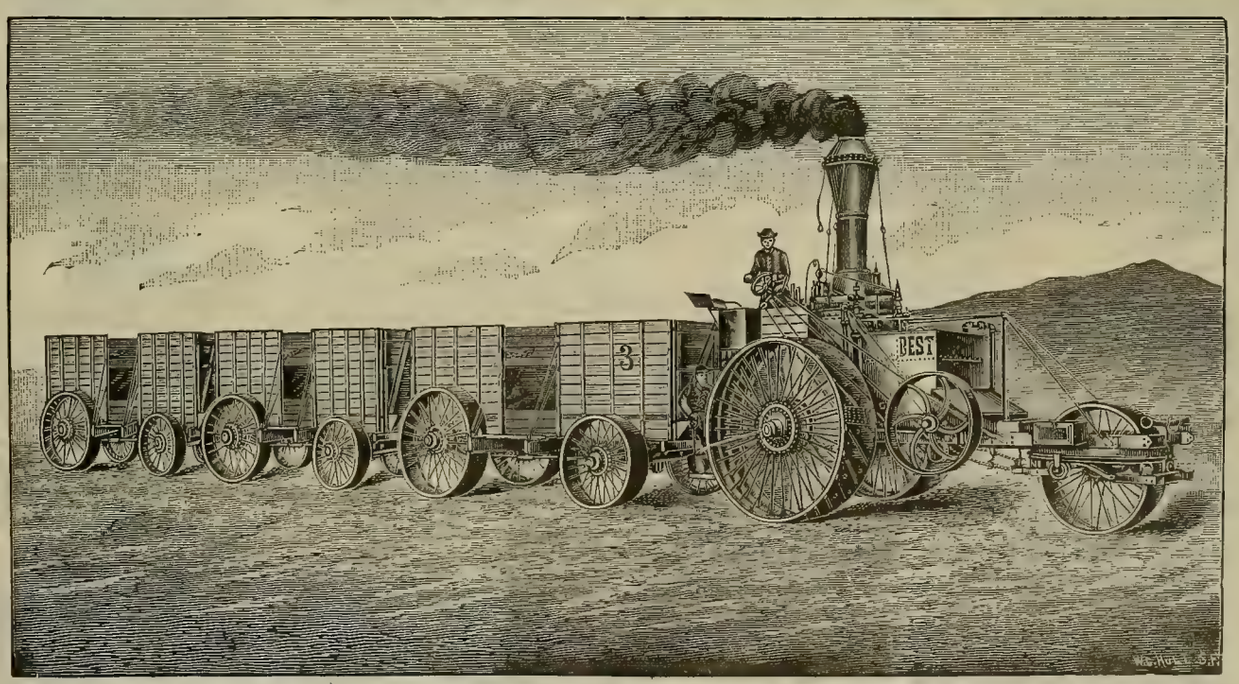
A REVOLUTION IN FREIGHTING.



THESE WAGONS ARE ESPECIALLY ADAPTED FOR STEAM FREIGHTING; CAPACITY OF TRAIN 50 TONS.

"The Daniel Best" 50-Horse Power Traction Engine.

The most powerful and only Successful and Practicable Road Engine in the World. Over sixty of them in use in this State, and they are being Successfully and Profitably Employed in Hauling Log umber, Ore, Salt, Borax and other kinds of freight.

The work is being done **FIFTY PER CENT** Cheaper than it is possible to do with Animal Power. They can be operated over any ordinary road where it is practicable to use mules or horses, doing ie same work. They can ascend or descend grades as much as 20 to 30 inches to the rod, hauling their loads of 35 to 40 tons, depending upon the condition of the roads; loads may be increased to even reater amount on moderately level roads.

Send for descriptive Circulars and price List of Wagons and Engine. We solicit correspondence. No trouble to answer questions.

Estimates made for complete Steam Freighting Outfits. Address

THE JOHNSTON CONCENTRATOR.

DURABILITY, CAPACITY AND SIMPLICITY : : ARE ITS ESSENTIAL POINTS. : :

SAVES MORE VERY FINE SULPHURETS THAN ANY OTHER CONCENTRATOR MADE.

The Johnston Concentrator is slung with arms from above on an angle, giving it the oscillating motion that makes it a perfect machine. This undulating motion immediately settles the sulphurets, retaining all amalgam, leaving sulphurets very clean, one 6-ft. Johnston doing the work of two 4-ft. belt machines.

PATENTS

DEWEY, STRONG & CO'S PATENT AGENCY.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American reports, with full copies of U. S. Patents since 1872. All worthy inventions patented through DEWEY, STRONG & CO.'S Patent Agency will have the benefit of a description in the *Mining and Scientific Press*. We transact every branch of patent business, and obtain patents in all countries which grant protection to inventors. The large majority of U. S. and foreign patents issued to inventors on the Pacific Coast have been obtained through our agency. We can give the best and *most reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and circulars free.

MINING AND MILLING MACHINERY.

DOUBLE CYLINDER SINGLE DRUM HOIST.

THE above form of Hoist has certain features of construction which make it superior to all others. It is mounted on a single solid base, with standboard for the operator. The engines are reversible link-motion and the drum is fitted with post-brakes and helical teeth, which assure quick and safe operation. The design is compact and superior and the construction strong and substantial. We furnish them either with or without clutch pinions. The above cut illustrates an 8½ inch by 10 inch. Other sizes in stock and built to order.

Dewey, Strong & Co., Patent Agents,

330 Market St., San Francisco, Cal.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY, STRONG & CO., Patent Agents, 330 Market St., San Francisco, Cal.

Market Reports.

SAN FRANCISCO, March 30, 1899.

SILVER. — London, 27¼d; New York, 59½; San Francisco, 59½; Mexican Dollars, 47½@48. New York exchange, sight, 15; telegraphic, 17 cents premium.

It is calculated that more fresh silver was added to the world's supply in '98 than in any year except '92, the total being 190,000,000 ounces, as compared with 183,096,000 ounces in '97 and 165,100,887 in '96. The market value was $105,000,000. In production the United States led last year with 60,000,000 ounces, Mexico coming next with 55,000,000. The average price for the year was 58.26 cents per ounce in New York, giving the silver dollar a bullion value of about 46 cents. The highest price in New York last year was 60.68 cents per ounce in September, and the lowest was 54.90 cents in March. A large increase is reported in the use of silver in the arts. A moderate demand for the metal continues in Asia. China, Japan, India and the Straits Settlements took 49,350,000 ounces from London, 12,990,000 from America and 7,000,000 from Australia. France coined some silver, and Russia a small amount. Spain wanted silver to scale down its obligations, but could not raise the money to pay for the bullion.

LEAD. — New York reports "barely steady," $4.37½ bid, $4.40 asked; brokers' price, $4.20.

Local, pipe, 7¼@7½c; sheet, 7¼@8¼c; pig, 7c; bar, 7¼c.

COPPER. — New York reports Lake unchanged; $17.50 bid, $17.75 asked; brokers' price, $17.75. Local, bar, 24c per lb.

IRON.—American, soft, $22@24 per ton; Scotch, $27. Local bar, 2½c per lb.

STEEL.—12½c per pound.

TIN.—Pig, 30c per lb.; Bar, 35c. New York reports unchanged, $24.15 asked.

ANTIMONY.—In San Francisco 1000 pounds and upwards, 10c net; 300 to 500 pounds, 11c; less than 100 pounds, 15c.

BABBITT METAL.—No. 3, 8¼c.

QUICKSILVER.—Local, $42.50@43; export, $39@39.50; carload lots, special rates.

PLATINUM.—London, 64s per ounce; New York, $16.50; San Francisco, $17. In '67 platinum sold for $4.40 per ounce. From that point the price advanced steadily until a corner was organized in '89, which put the price up above $20 per ounce. The great advance in price restricted the demand and resulted in a greatly increased visible supply. This metal was dumped upon the market in '92, and the price fell to $6.50, but not to the original quotations. After this slump the market quickly recovered to $12@16 per ounce, and the quotations have ranged within those limits the most of the time since that date. Increased demand now tends the price upward again.

POWDER.—F. o. b., San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15¼c; less than one ton, 17¼c. No. 1* 60%, carload lots, 13¾c; less than one ton, 15¼c. No. 1** 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2* 35%, carload lots, 9½c; less than one ton, 11¼c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

FUSE.—Triple tape, $5.10 per 1000 feet; double tape, $4.35; single tape, $3.45; Hemp, $8; Cement No. 2, $4.35; Cement No. 1, $3.45.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9.

COAL.—San Francisco coast, yard prices:

Wellington	$8 00	Coos Bay	$5 00
Seattle	6 00	Southfield	7 50

Cargo lots, Eastern and foreign:

Wallsend	$ 7 50	Cumberland	$ 9 00

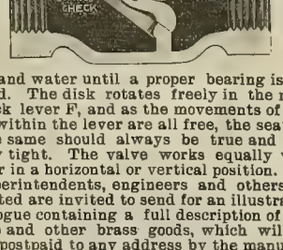
New Re-grinding Swing Check Valve.

Herewith is illustrated a swing check valve that the manufacturers consider has some desirable points that merit its favorable consideration, they being in the line of improvement. It appears simple, efficient and is warranted to be tight. The re-grinding is quickly accomplished at any time by unscrewing the cap B from the shell A, inserting screw-driver into the slot E and rotating the disk back and forth with a little grinding



sand and water until a proper bearing is obtained. The disk rotates freely in the neck of rock lever F, and as the movements of the disk within the lever are all free, the seating of the same should always be true and perfectly tight. The valve works equally well either in a horizontal or vertical position.

Superintendents, engineers and others interested are invited to send for an illustrated catalogue containing a full description of the above and other brass goods, which will be sent postpaid to any address by the manufacturers—The Wm. Powell Co., 2525 Spring Grove Avenue, Cincinnati, Ohio.

Assessment Notices.

EUREKA CONSOLIDATED DRIFT MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Forest Hill Divide, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 9th day of March, 1899, an assessment (No. 17) of one-half of one cent per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 1209 Claus Spreckels building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 11th day of April, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 28th day of April, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

J. J. CRAWFORD, Secretary.

Office—1209 Claus Spreckels building, San Francisco, California.

BEST & BELCHER MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Virginia District, Storey County, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the seventh (7th) day of March, 1899, an assessment (No. 66) of ten (10c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, Room 33 Nevada Block, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the tenth (10th) day of April, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the second (2nd) day of May, 1899, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

M. JAFFE, Secretary.

Office—Room 33 Nevada Block, No. 309 Montgomery street, San Francisco, California.

HEAD CENTRE CONSOLIDATED MINING COMPANY.—Location of principal place of business San Francisco, California; location of works, Tombstone Mining District, Cochise County, Arizona.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 20th day of March, 1899, an assessment (No. 7) of twenty (20) cents per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, No. 310 Pine street, rooms 15 and 17, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 2nd day of May, 1899, shall be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 29th day of May, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

J. W. PEW, Secretary.

Office—No. 310 Pine street, rooms 15 and 17, San Francisco, California.

NATIONAL CONS. MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Rich Gulch, Shasta County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 20th day of March, 1899, an assessment (No. 6) of ten (10) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 773 Mission street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 8th day of May, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on THURSDAY, the 1st day of June, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

G. W. FLEISSNER, Secretary.

Office—773 Mission street, San Francisco, California. Office hours from 1 to 3 P. M.

MARINA MARSICANO GOLD MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Sunny Hill, Shasta County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 11th day of March, 1899, an assessment (No. 18) of 5 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, 217 Sacramento street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 17th day of April, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 8th day of May, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

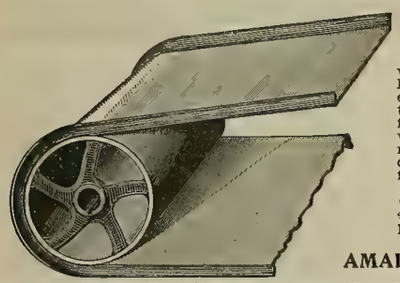
SPADONE'S CONCENTRATOR BELTS.

PATENTED.



This illustration shows the edge flanging outwardly as it passes over the pulley. This relieves the strain from the top and bottom of the edge by directing the strain automatically to the inside face surface of the edges. Heretofore all belts have been so constructed that when they pass over the pulleys or rolls, a direct strain comes upon the top or at the base of of the edges, causing the edges to break away from the body of the belts in a very short time. *We avoid this Mechanical Defect by our Spadone Curved Edge.* Belts made to fit any machine—4, 5 and 6 feet wide. Prices and samples on application.

AMALGAM PLATE CLEANERS.

Our Amalgam Plate Cleaners are made of Pure Rubber in moulds, thus insuring a plate cleaner which will not scratch the plates and a perfect edge which will clean the Amalgam plates evenly. They are made 6 inches long, 3 inches wide and ⅛ inch thick, making a convenient size to handle. Price by mail to any address, each 75 cents. Correspondence solicited.

Send us your order for Water, Air Drill, Steam, Suction and Fire HOSE, RUBBER BELTING, RUBBER PACKING and LEATHER BELTING.

30 and 32 FREMONT STREET, Telephone Main 1813. **SAN FRANCISCO, CAL.**

P&B BUILDING PAPER

The walls of a house are built for protection. If the sun and weather open up the sheathing, the rain or the air will get in and cause discomfort and doctor's bills. To prevent this the architect or builder uses building paper. There are many kinds, but only two classes—the poor and the good. P & B PAPER is good—the best. It is very strong, odorless, waterproof and airproof, and will not rot. Ask your dealer for samples, or write us for them. We are the makers.

ROPP STRAIGHT LINE FURNACE

FOR ROASTING, CHLORINATING AND DESULPHURIZING ORES.

Extracts from Letters Received from Mr. Philip Argall, Manager the Metallic Extraction Co., Cyanide, Colorado:

January 2, 1897.

"The roasting is invariably good. We can do 80 tons per day to 0.13% sulphur, when everything runs smooth. Our month record which, of course, includes all delays, is 1700 tons, from 1.94% sulphur to 0.16%."

February 19, 1897.

"Our furnace is now running very nicely indeed, averaging 90 tons per day to 0.10% sulphur, and doing excellent work; in fact, it has improved right along and we are highly pleased with it.
"For 24 hours ending 7 A. M. to-day 102 tons were roasted."

The **ROPP FURNACE** is now in successful operation at the following reduction works: The Hanauer Smelting Works, Salt Lake City, Utah (one furnace); The Metallic Extraction Co., Cyanide, Colo. (one furnace); The Colorado-Philadelphia Reduction Co., Colorado City, Colo. (three furnaces); The Selby Smelting & Lead Co., Selby, Cal. (two furnaces); The Mount Morgan Gold Mining Co., Rockhampton, Queensland (one furnace); Broken Hill Proprietary Co., Broken Hill, New South Wales (four furnaces); Puget Sound Reduction Co., Everett, Washington; Colorado Ore Sampling & Reduction Co., Cripple Creek, Colo.; Consolidated Kansas City Smelting & Refining Co., for the Arkansas Valley Smelting Works, Leadville, Colo.; Robert Lanyon's Son's Spelter Co., Iola, Kansas (two furnaces); Mountain Copper Co., Ltd., Keswick, Cal.

The Equipment and Development of New Mines.

When a new mine is to be equipped and developed, it is desirable to place on the property machinery suitable for the purpose of development and to block out the ground as expeditiously and cheaply as possible. There is much diversity of opinion among mine superintendents as to what comprises a proper equipment and also as to what lines of development should be followed. As a matter of course, the plan adopted will be influenced by the conditions under which the mine will operate. As all undeveloped mines are most uncertain as to size of ore deposits, value of ore, amount of water that may be encountered and character of ground, it is wise to anticipate difficulties, even in a mine which at or near the surface seems more favored than some of its neighbors. As the quantity of ore that may be found is unknown when development commences, experience has shown that it is unwise to put up an expensive hoisting plant until it has been determined that such a plant would be necessary. Veins large at the surface may not continue large in depth, and even should they do so, the value of the ore may be such as to afford no profit, in which case no hoist would be required at all. On the other hand, some mines, small and low-grade at and near the surface, in depth develop large ore bodies of great value.

In such cases the small prospecting plant may be replaced by such a one as the development of the mine may justify. For a relatively small sum of money a good hoisting plant may be set up which will hoist at moderate speed 1000 pounds of rock at a load, with which a large shaft may be sunk many hundreds of feet.

Abundant power should always be provided, however, whether steam, water or electricity be employed, for the reason that many shafts comparatively dry near the surface become very wet in depth. When a large influx of water occurs, whether it prove to be a permanent and constantly increasing quantity as depth is attained, or whether, after a sudden rush of water, it is found to steadily decrease as pumping or bailing is continued, abundant facility for handling a larger quantity of water than has ever been encountered should always be at hand. Large valve buckets are very useful as auxiliary to pumps when working in levels, but a valve bucket is useless when sinking.

When the shaft has reached a depth of 500 to 1000 feet and levels run along the ore body or vein, crosscuts made and raises put through, the manager has a definite idea of the quantity of material exposed possessing a net value, and can then put in a hoisting plant suited to the requirements of the mine. It would be unwise to put in a hoist capable of raising 2000 or 3000 tons of ore in twenty-four hours at great velocities, when it would be found difficult to supply a 40-stamp mill with 100 tons of ore daily from a small vein. Very large ore bodies may be extracted hurriedly, the chambers timbered and filled as the work progresses. A mine capable of supplying 1000 tons of ore or twice that amount daily should be equipped with engines capable of raising that amount and doing it easily.

What applies to hoisting engines applies with equal force to metallurgical plants. The character and capacity of plants for the beneficiation of ores cannot be determined upon with safety until the development of the mine has demonstrated its capacity and the character of the ore. Mistakes in this direction are probably of less frequent occurrence than formerly, but it is not many years since it was not uncommon to see a smelter erected to treat dry ores and wet-crushing stamp mills built to treat lead carbonates and galena. There are very few ores indeed that cannot now be successfully treated by some one of the many processes in practical operation in every corner of the world. All that now remains to do is to ascertain the one best adapted to the ore in question, all things being taken into consideration, as cost of transportation, chemicals, fuel, labor, etc. Improvements and lower cost in the processes of to-day may be anticipated and new processes which will treat some ores successfully may be expected to supercede processes now in use.

In shaft sinking it is cheaper to cut out the stations when the various points at which levels are to be run are reached, and the levels should also be started at such time, sinking only enough to afford a sump below the level. In mines where it is evident a large amount of ore is to be handled, where skips or buckets are used for hoisting, it is very good practice to cut out under the floor of the level a space for an ore bin or pocket into which ore or waste may be dumped from cars trammed to the shaft from the faces of the drifts or from the chutes. This provides an economical means of loading skips and hoisting may be carried on independent of stoping and tramming. The first level in the mine should be run from the shaft at a point above which little or no stoping will be done, at least not for a long time. Having run this level work in it may be discontinued for the time and the shaft carried on down to the next level. It is not necessary to stop shaft sinking to run the level, except while cutting out the station, the ore pocket and starting the level. Having run the second level, the location of raises may be established, and when this is done winzes may be started in the level above at points on the vein immediately above the raises. By this means the connection is more quickly made, and it will be found that the employment of the extra men on the windlass or auxiliary hoist at the winze pays, for men will not and cannot work to advantage in a hot raise laden with powder fumes. Good ventilation is a most important factor in the economy of mining.

GENERAL VIEW OF MAGALIA DRIFT MINE, BUTTE COUNTY, CAL. (See page 372)

The detail of arrangement of mill holes is so various that that feature need not be discussed. When opening the third level it will be found advantageous not to put the next series of mill holes directly below the series above, but at some little distance to one side, which greatly lessens the likelihood of accident.

In recent years a great many shafts are being sunk in the walls of the vein in preference to sinking on the vein. This is usually, though not always, good practice. Where the fissure is known to be soft and accompanied by swelling ground next to the fissure, it is far better to sink in the wall, and, in the case of a wide vein, always in the foot wall; in a small vein, or one of moderate size, either wall may be safely chosen, though the foot wall is preferable. Of course, such conditions as are referred to can only be known by proximity of a developed mine on the same vein, as was the case of the Argonaut mine, at Jackson, Amador Co., Cal., where the extensive development of the Kennedy mine adjoining showed that a shaft in the wall was to be preferred to one in the fissure. A prospect shaft should always be sunk on the vein, when adjoining mines give no indication of what may be expected, and, if the development be satisfactory, a permanent working shaft may be sunk at a point with reference to the position of the ore shoots and their trend. Tunnels for development should always, where possible, be driven on the vein.

MINING AND SCIENTIFIC PRESS.

ESTABLISHED 1860.

Oldest Mining Journal on the American Continent

Office, No. 330 Market Street, San Francisco, Cal.

Telephone Number, Davis 771.

ANNUAL SUBSCRIPTION:

TWO INTERESTING FACTS.

In all the States of the Far West and the Pacific Slope, consisting of California, Oregon, Washington, Idaho, Montana, Wyoming, Colorado, New Mexico, Arizona and Utah, the largest circulation credited to any publication devoted to engineering and mining is accorded to the MINING AND SCIENTIFIC PRESS, a weekly, published at San Francisco, Cal.—*American Newspaper Directory.*

Among the engineering and mining papers in California, none has credit for so large a regular issue as is accorded to the MINING AND SCIENTIFIC PRESS, published weekly at San Francisco. In fact, it fully equals five times the combined issue accorded to all the others.—*American Newspaper Directory.*

THE Central Eureka mine, near Sutter Creek, Amador county, Cal., is making a record in shaft sinking, the average being 5 feet per day, at a depth of nearly 1200 feet.

THE recent report of the directors of the Geldenhuis Estate Co. of Johannesburg, S. A. R., shows the affairs of the company to be in excellent condition. Large profits are realized from the operation of their several mines and dividends to the amount of 97½% paid, but a large cash balance is also retained in the treasury for contingencies—a practice well worthy of emulation.

BRITISH COLUMBIAN mine owners are agitating a plan to have lead mined and smelted in Canadian territory and refined in the United States, permitted to re-enter Canada duty free. At present 6,000,000 pounds of lead are annually shipped into Canada, upon which the duty is 15%, and on this the lead manufacturer has to pay the cost of freight to London and return, as well as the duty of 15%.

COMPLAINT is made in British Columbia that the Canadian Pacific R. R. Co. is secretly working against its openly expressed intention to further British Columbia lead smelting by keeping its Trail smelter in operation. It is held that the January meeting at Spokane, Wash., between its representatives and those of the United States smelters, resulted in an agreement that the latter should pay the former $5.50 a ton on all lead ore carried from British Columbia into this country, and that the Canadian railway corporation proposes to charge the same for treatment at Trail as that charged by the United States smelters. Omaha smelter charges are $8 per ton: it costs British Columbia lead miners $20.50 per ton to send their ores to the Omaha smelter and have them there smelted, and the British Columbia people think their local railway company ought to make reduction on treatment charges, while they protest against the bonus secured on the American business. The mistake the British Columbia people make is in assuming that a railway company's business is run on a philanthropic basis. Canadian Pacific stockholders want dividends. The business of that corporation is primarily to make money in the carrying trade. Where it enters into the business of smelting that must give way to the primary requirements of the main purpose—to run a railroad at a profit.

Copper Values With Depth.

Natural interest is felt in recently published assertions in Eastern papers that Lake Superior copper mines are growing leaner with depth, and decreasing in ore value as the workings go down. Apart from the inevitable "working" of the street, on any statement and with any argument to put stock up or down, the matter is one deserving notice on general grounds. If Michigan copper ore veins grow poorer with increased depth, the fact is of interest to copper miners everywhere. It has been generally assumed that at the depth of a mile below the surface some Lake Superior copper mines showed no exhaustion of quantity nor any diminution in value, and that the downward limit of profitable working could be determined only by the degree of heat in sinking on an amaygdaloid lode. Such view, while attacked, has not been overthrown, and the arguments directed against it seem susceptible of contradiction. The chief argument advanced by those who claim the Lake Superior copper mines are petering out is an array of figures showing lessened percentage of copper in the ores mined and milled in the Tamarack, Atlantic and Quincy in '98 as compared with '87, '86, and '76. While this certainly would, by itself, seem to substantiate the claim of decreasing values, yet every miner knows that unless accompanied by full and accurate details, such data are of no value. Such figures may upset the street, may bull or bear the stock, but in the absence of corroborative showing no miner will consider the question more than raised. Assuming, for the sake of argument, that everything claimed by the published figures referred to may be so, they prove nothing. True, they suggest that as the workings extend downward the ore is poorer, and thus directly imply that a limit will be reached where the ore has not sufficient percentage of copper to pay for extraction. But the question so important to the copper miner everywhere—does the ore give out at great depth?—is not thus determined. Indeed, it is probable that were full and exact data forthcoming, the truth would be apparent that so many other things enter into the problem as to indicate that the reverse of the assumption was in line with the facts, and that the ore averages were up to former standards. "Averages" are referred to. It is only by "averages" that the increasing or decreasing value of a great mine can be rightly determined. In such enormous depths as those attained in the Lake Superior district the picking out of the work of isolated years constitutes misleading comparison. Take, for example, the Quincy mine, one of the three mentioned. In a letter to the Boston News Bureau, H. J. Stevens, a well-informed local correspondent, shows that "the Quincy mine was merely a fair one to a depth of 1000 feet. From 1000 feet to 1200 feet the rock was so lean that it did not pay for stamping. Below the 1200-foot level the mine became far richer than ever before, and has remained so to the present depth of approximately 4500 feet." He also brings up a factor of considerable importance in showing that in that district closer milling is now the rule. "It costs but one-half to two-thirds as much money to stamp a ton of rock as it cost ten to twelve years ago, thanks to improved machinery and methods. This enables mine managers to stamp rock at a profit which by reason of its paucity of metal must have been discarded one or two decades ago. This reduces the percentages from rock stamped, but increases the percentages from rock mined." Regarding another of the mines mentioned—the Atlantic—it is further in evidence that in that mine every pound of rock from wall to wall, about 85 feet across, goes under the stamps, and it is manifest that when so much inevitably poor rock thus goes through, the percentage of copper to the ton stamped must as inevitably be low. The case seems in some respects parallel to that of so many California gold quartz mines that, though now paying handsomely, were at one period on the point of abandonment because they did not "go down." So far as observable, there is nothing in the present onslaught on the Lake copper mines stock to warrant cessation of downward operations on copper properties.

THE last California Legislature appropriated $130,000 to pay the expenses of collecting and maintaining an exhibit in Paris in 1900. It provides for the appointment of three commissioners to the Paris Exposition, to have control of funds and exhibits. They are to get $5000 each and all expenses, and each must give a bond to the State, in the sum of $10,000. Of the $130,000 the mining industry of the State is to have $25,000. Any additional amount for appropriate mining display at the exposition must be otherwise provided. The mineral industries of the entire United States have been allotted 8000 superficial square feet of space for exhibition purposes at the exposition. Of this area nearly one-half will naturally be required for aisles to afford passageway through the exhibits, leaving probably 5000 square feet of actual exhibiting space. To fill this strip, about 50x100 feet, the United States would probably be represented by the iron and coal mines of Pennsylvania, Ohio and Alabama; the iron mines of Michigan and Minnesota; the copper mines of Michigan, Montana and Arizona; the gold and silver mines of California, Colorado, Arizona, Utah, New Mexico, Montana, South Dakota, Wyoming, Idaho, Washington, Oregon and Nevada, and the lead and zinc mines of the Mississippi valley States. Here are no less than eighteen States—and there are still others. If each State is given an equal amount of space, which they undoubtedly have the right to demand, the allotment to each will be about 280 square feet, which would be covered by a line of flat show cases 8 feet wide and 35 feet long. It becomes at once apparent how ridiculously inadequate the space will be should there be a fairly representative exhibit. It is equally apparent that any mining State that wants proper representation should appoint its commissioners and begin its work, the sooner the quicker.

"WHAT did the last Legislature do with California mining law?" is the gist of numerous questions received since the California Legislature adjourned. It repealed the Act of March 27th, '97. Nothing else it did about mining is of effect. It passed a law providing how claims should be located, but the Governor refused to sign it. So that the California miners are just where they were before the Act of March, '97, was passed. The Legislature which adjourned in '97 passed an Act prescribing the manner of locating mining claims, recording notice of location, amending defective locations, providing for the deposit of district records with county recorders, and prescribing the effect to be given recordation of notices of location and affidavits. Some things were badly needed then, and are as badly needed now. One was a plain, clear, precise definition of what constitutes proper marking of location. This the Act of '97 did not contain. It did contain several provisions that were desirable, but was defective and unsatisfactory. Nothing was done by the latest California Legislature regarding the State school lands. The preceding Legislature, however, repealed the Act of March 28th, '74, providing for the sale of mineral lands in sections 16 and 36—school sections ceded to the State by the Federal Government. This matter is of considerable importance. The repeal, in effect, relinquished any State claim to mineral lands in the township sections specified, they being declared to be "free and open to exploration, occupation and purchase of the United States, under the laws, rules and regulations passed and prescribed by the United States for the sale of mineral lands."

THE recent decision of Judge Hallett in the U. S. Circuit Court of Colorado, in the case of the Matoa Co. vs. the Chicago-Cripple Creek Co., is important in that it determines the rights of both tunnel locators and those who were previously located on the line of the tunnel. According to this decision, the locator of a tunnel site cannot drive his tunnel through ground previously located by others without an agreement with such prior locators. The tunnel locator is entitled to 3000 feet of every vein he may discover crossing his tunnel—1500 feet on each side—whether apexing on the surface or not, and not previously claimed; but he may not enter within the lines of a previous locator in search of such veins.

Concentrates.

THE better way to write the date of the present year in Roman letters is MCIM.

THE next session of the Northwest Mining Association will be in Seattle, Wash.

EMPLOYES of the Mountain Copper Co., Shasta Co., Cal., pay an annual hospital tax of $12 to the company.

F. B. CRONIN of Melbourne, Australia, announces an invention "for saving gold by means of mineral oil."

AN experiment is not an experiment for practical purposes unless every condition of the larger plan in view is included.

TEN per cent copper ore should pay handsomely under ordinary conditions. Quincy, Mich., copper ore averages 8.5%.

THE Marconi system of telegraphing through space without wires was illustrated and described in detail in the issue of Jan. 8th, '98.

THE "Boise basin" is not a bowl-shaped depression, but a section of country made up of the valleys of the Weiser and Payette rivers, Idaho.

THE pumice mined at Black Rock, Utah, is principally bought by the Chicago Pumice Co., the finished product selling in that city at $25 to $33 per ton.

THE last U. S. Congress appropriated $15,000 for the maintenance of the California Debris Commission, and traveling expenses for the Commissioners when engaged in their work.

A NEW mining law goes into effect June 21st, '99, in Colorado of interest to many there. It abolishes the extra trial in ejectment suits which have hitherto constituted a large part of Colorado's mining litigation.

A TECHNICAL description of the process of making briquettes from fine ores for smelting was published in the issue of Feb. 18th, '99, page 175. Parke & Lacy Co., 23 Fremont St., San Francisco, supply those machines.

CONSUL URBAIN J. LEDOUX of Three Rivers, Quebec, furnishes a report of Canada's mineral productions in '98. Of the total output of metallic products, valued at $21,622,601, $13,700,000 was gold, $10,000,000 representing the Yukon output.

THERE is nothing unusual in a daily crushing of five tons rock by a stamp. Such duty is often exceeded. It is not uncommon for a California stamp mill to average five and one-half tons of rock per stamp per twenty-four hours. for a month at a time.

IT has been asserted without contradiction that the first inventor of the modern way of hanging up a stem in a stamp battery was a German who made and put in use such a device at the Reese mill, Sierra Buttes gold mine, Sierra Co., Cal., in the early fifties.

A PARTIAL bibliography of articles on the cyanide process, the name of the paper in which it appeared, the name of the author, and the date of appearance, was published in the issue of Nov. 28th, '96. Of about 200 articles so classified, 51 appeared in these columns.

WATER may be removed from tanks or mines or other excavations by means of the syphon to a depth where the atmospheric pressure equals the weight of a column of water. Theoretically this is 33 or 34 feet at sea level, but this diminishes with increasing altitude.

OPTIONS on mining claims to the amount of about $2,000,000 in the Buffalo Hump region in Idaho, since its discovery a few months ago, is somewhat unusual, in consideration of the fact that its principal mine—the Big Buffalo—is reported to be no more than a good prospect.

ITALIAN miners are increasing in numbers in Colorado. Colorado mine owners who employ them say about 60% of their earnings is sent back to Italy. They are all union men and get the union scale of $3 per day, of which they save $2. Few are married, and fewer naturalized.

URANIUM, or pitchblende, is usually associated with lead and silver, sulphur and arsenic. The pure mineral contains only the oxide. That is used in imparting fluorescence to glass and decorative painting. Ore containing less than 10% uranium oxide is of little commercial value.

THE Superintendent of the Mint at San Francisco may purchase mutilated and uncurrent silver coins in sums in excess of $3 at the price fixed by the Director of the Mint for silver contained in gold deposits. Such coins should be sent to the Mint by registered mail or express, prepaid.

A GOOD flux suitable for many ores is composed of six lbs. bicarbonate of soda, four lbs. litharge and two lbs. borax glass. A cheaper composition, and one that usually gives satisfaction, is made of six lbs. bicarbonate of soda, four lbs. thirteen ozs. litharge, and three lbs. powdered borax.

THE present status of California mining law is precisely what it was before the law of March 27, '97, was passed. That law prescribed the manner of locating mining claims, recording notices, affidavits, etc., and was repealed by the recent Legislature. It ceased to be a law on the 1st inst.

THE battleship Iowa, now in San Francisco bay, was begun Aug. 5th, '93, and was delivered to the Government in August, '97. She is 360 feet long, 72½ feet wide, draws 24 feet of water; her engines had an indicated horse power of 11,000. Her rated speed is 16 knots (17.76 miles) an hour. She cost $4,000,000.

A COLORADO metallic extraction company's circular contains some remarkable statements. Not content with the customary "revolutionizing the science of gold extraction," which, of course, is incidental, this company "has already treated successfully a moss which grows on the river on which it proposes to erect a mill."

TO FIND the total pressure of quiet water on a dam, tank, lock gate or other surface, multiply together the area in square feet of the surface sustaining the pressure, the vertical depth in feet of its center of gravity below the surface of the water, and the constant number 62.5 and the product will give the pressure in pounds.

AN assignment of a patent, either in part or the whole patent, must be made in writing and duly recorded. Any transfer short of this is a mere license, gives licensee no title in the patent and no right to sue in his own name for infringement. Any rights of the licensee must be enforced through or in the name of the owner of the patent.

WITH ordinary precaution there need be no danger of accidents from the use of a gas or gasoline engine in or around a mine. Of course, where explosive gas is generated, a gasoline engine igniting from an external flame is not advisable; but, ordinarily, no greater degree of precaution is necessary than in the use of any other form of applied power.

MARIPOSITE is a scaly micaceous mineral of beautiful emerald green color, and occurs abundantly along the gold belt of California, being usually associated with a dolmitic rock, which latter sometimes graduates into ankerite. Mariposite was first described by Prof. Silliman, Dec. 2, '67. Its composition is variable. It never occurs massive, but always as a scaly mineral.

PROBABLY the highest dredging for gold anywhere is that at Breckenridge, Summit Co., Colorado, over 9000 feet above the sea. Placer mining goes on in that locality near the source of the Platte river, at Mt. Lincoln, which is 14,000 feet above the ocean level. An illustrated article on page 376 gives further details of placer and quartz gold mining in high altitudes in Colorado.

THE thirty forest reservations of the United States embrace an area of 40,000,000 acres in thirteen States and Territories. Seven are in the State of California, the largest of which—the Sierra forest reserve—includes 4,006,000 acres. Within the past thirty-five years it is estimated that 11,000,000,000 feet B. M. of timber on public land have been destroyed by forest fires.

IN constructing dams, piers, walls or other structures of similar character, it is very essential that the foundation be placed on rock when possible, for when water is able to find its way underneath such structure, the upward hydrostatic pressure of the water has a tendency to lift the structure with a force equal to the weight of the water displaced by the structure.

IN his recent report, Le Neve Foster, Inspector of Mines in Great Britain, presents figures showing that the United States leads in the world's production of iron, Great Britain second, Germany third. Spain produces the largest quantity of lead, the Malay peninsula nearly two-thirds of the world's supply of tin, and Upper Silesia makes Germany foremost as a zinc producer.

THE directors of the Mountain Copper Co., Ltd., Keswick, Shasta Co., Cal., report that the revenue for '98 showed a gratifying increase, and the net profits, after deducting all costs and charges, amounted to $816,160. It is proposed to pay on the 5th inst. a final dividend of 5%, making 7½% for the year, to place $345,000 to the credit of the reserve and depreciation fund and carry forward $640.

LOWERING of treatment charges; increased transportation facilities; better knowledge of processes and surer results; reduced cost of machinery and supplies; competition of labor and competition of capital; constantly increasing demand for the product; the certainty of science as applied to commercial effort—these are among the causes of the changed conditions and the great advance in the mining industry.

THE strength of a man for continuous work, maintained for eight hours a day, is estimated as one-tenth of a horse-power. The engines of the battleship Oregon develop and maintain 9500 H. P. To maintain the same power by human muscles—for instance, by men turning cranks geared to the screw-shafts—would require 285,000 men, 95,000 on each eight-hour shift—more than all the men in California.

AN assay office, as at Helena, Mont., Boise, Idaho, Denver, Colo., or Carson, Nev., will advance 90% on all the gold left there, and, when the actual value is determined, will settle by check on the sub-treasury. All settlements are on the basis of fine gold. British gold is eleven-twelfths fine; American, French and German, nine-tenths. American gold coin is received at its face value till it has lost one-half of 1% by wear, after which it is received by weight only.

THE production of the Chapin iron mine, the largest in the Menominee range, Michigan, in '98 was 724,768 tons. It has produced up to date nearly 8,000,000 tons of ore. The Hamilton shaft on this property is down 1460 feet, equipped with engines taking five tons at a lift. The pumps have a capacity of 1700 gallons per minute. The main levels are 100 feet apart, divided by three sub-levels with intermediate levels where desired. Small timber only is employed, the Nevada system having been abandoned.

ACCORDING to the provisions of the recent California appropriation bill, the Governor is given the right to usurp the office and prerogatives of the State Mineralogist. The bill appropriates $50,000 for the maintenance of the Mining Bureau, directs that $20,000 of this shall be expended in field work and vests in the Governor the right of appointment of the assistants in the field and the fixing of their respective salaries. This takes that whole matter out of the hands of the State Mineralogist and leaves him nothing more to do than attend to the office work and its supervision.

UNDER date of the 1st inst., a prominent California mining superintendent writes from El Dorado county: "While I am taking several other mining journals, there is not one of them that compares in helpfulness and general practical mining information to us right here on the ground with the MINING AND SCIENTIFIC PRESS. I find its files a most valuable reference book on mining matters." Another Colorado mine superintendent writes: "Send two additional copies to ——, foreman, and ——, the millman, this address, and send bill to me. It is a good investment."

IN the case of Black vs. Elkhorn M. Co. (163 U. S. 445), the United States Supreme Court says: "The interest in a mining claim, prior to the payment of any money for the granting of a patent for the land is nothing more than a right to the exclusive possession of the land based upon conditions subsequent, a failure to fulfill which forfeits the locators' interest in the claim. To sum up as to the character of the right which is granted by the United States to a locator, we find: First, that no written instrument is necessary to create it. Locating upon the land and continuing yearly to do the work provided for by the statute gives to and continues in the locator the right of possession as stated in the statute. Second, this right, conditional in its character, may be forfeited by the failure of the locator to do the necessary amount of work; or, if, being one among several locators, he neglects to pay his share for the work which has been done by his co-owners, his right and interest in the claim may be forfeited to such co-owners under the provisions of the statute. Third, his interest in the claim may also be forfeited by his abandonment, with an intention to renounce his right of possession. It cannot be doubted that an actual abandonment of possession by a locator of a mining claim, such as would work an abandonment of any other easement, would terminate all the right of possession which the locator then had."

AT the close of the 56th Congress was passed a law which enacts "that the Secretary of War, in carrying out the provisions of any Act of Congress providing for the restraining or impounding of mining debris in California may, in his discretion, when in his judgment the aggregate of appropriations already made by said State and Congress and available therefor are sufficient to complete the same, undertake the work necessary thereto by hired labor and by purchase of supplies and materials therefor, and may accept payments on account thereof as the work progresses under and according to the provisions of the Acts of the Legislature of said State for such purposes."

ONE theory of the genesis of the "mother lode" in California is that at the time of the upheaval of the Sierra Nevadas, and the disruption and tilting of the adjacent rocks, a series of fissures were formed which were subsequently filled with quartz and other mineral matter by alkaline water at a high temperature. Alkaline solutions, at a high temperature and under pressure, will dissolve large amounts of quartz, which is deposited in a crystalline state on the cooling of the solution. How the gold got there is also the subject of much discussion. A great deal has been written on this subject. What is believed to be the latest and best article thereon was written for this paper by Ross E. Browne, and appeared in the issue of Jan. 29th, '98.

AT Trenton, New Jersey, on the 4th inst., articles of incorporation of the American Smelting Refining Co., with a capital of $65,000,000, were filed with the Secretary of State. The company is empowered to mine, smelt and refine ores, minerals and metals. The incorporators are W. E. Dwight, T. M. Day Jr., J. J. Tracy, H. W. Thomas and A. P. Bartlett, all of Jersey City, N. J. The entire prospectus of the company was published on page 297, of the issue of March 18th. It is noticeable that since that publication and the accompanying inference of a prospective 10% advance in the price of silver thereby, there has been a corresponding advance in Mexican Central railroad securities. In '98 a 10% advance in the price of silver would have increased that road's net earnings for the year, on a U. S. currency basis, $208,000.

ANSWERING H. S., Anaconda, Mont., and L. T., Phœnix, Ariz., one matter can be best disposed of by reference to the fact that while a pound, troy, contains 5760 grains, a pound, avoirdupois, weighs 7000 grains. Concerning the declination of the advertisements, it is somewhat difficult to make it clear to one who does not understand it without explanation, why this paper will not print an advertisement pure and simple, in form identical with the regular body of reading matter in the paper. The motive for such refusal rests upon an unwillingness to have anything which is paid for as an advertisement go to the reader in a form which would lead him to believe it to be editorial matter, and, therefore, not paid for. It is a simple question of integrity between the publisher and the reader, and as such will, it is believed, command respect.

THE work or actual labor on a mining claim necessary to hold it need not necessarily begin on the first day of January, that date being specifically named as limiting the time when such work shall begin. The necessary $100 worth of development work on an unpatented mining claim can begin on any day after the first day of January next succeeding the date of location; but must all be done within that year; that is, supposing a mining claim was located to-day—April 8th, 1899—the locator has until Dec. 31st, 1900, to do the necessary development work on that claim enabling him to hold it. Any work done on that claim between now and Dec. 31st, '99, does not count on next year's necessary assessment work, and no work is necessary between April 8th, '99, and Dec. 31st, '99, to hold it; but $100 worth of work must be done on the claim between April 8th, 1899, and Dec. 31st, 1900, to hold it.

SO FAR as known, the "Ashcroft process" has not been a satisfactory commercial success. Effort is now making in London to experiment with a similar electrolytic process on a smaller scale. This modified process, which is claimed to be cheaper, mainly consists in stirring the crude ore into a bath of melted zinc chloride contained in a cauldron heated from beneath. A little molten lead in the bottom of the cauldron alloys with and removes the silver and gold from the ore. The rich lead is then withdrawn and the mixture of sulphides and chlorides of lead and zinc subjected to the action of an electric current. Free sulphur is given off in the form of vapor in a practically pure state, and is sublimated. Of the metals the lead is first deposited in a molten state, and afterwards the zinc. The cost of the process is stated to be $10 per ton. From a commercial point of view, the statements made concerning the matter are not alluring.

AT St. Louis, Mo., last week, Judges Caldwell, Sanborn and Thayer of the United States Court of Appeals rendered a decision in the case of the Durant M. Co., plaintiff in error, against the Percy Con. M. Co., in error, to the United States Circuit Court of Colorado. A decree of the lower Court, granting the Percy Con. M. Co. $11,431 damages for ores taken from its property by the Durant M. Co. was reversed on the ground that one who ignorantly removes ores from another's claim is liable for damages to the value of the ores and no more. An important point in mining law is passed upon by this decision. The question has often arisen in the courts as to the extent of the liability of those who have unknowingly removed ores from another's mining property. It makes considerable difference in the amount of damages that any Court may probably hereafter allow in similar cases. In this particular case the difference amounts to $8600. When the case was heard by Judge Hallett, the jury was instructed that it would be impossible for a company to make a mistake underground and dig into another company's claim, and that the trespassing company was therefore liable for the full amount of the damages sustained. This would permit of a verdict for the full value of the ores, the cost of extraction not being considered, and in addition thereto a reasonable amount of exemplary damages as a penalty for encroachment. The higher Court holds that a miner is just as likely to make a mistake underground as above.

The Magalia, Cal., Drift Mine.

Written for the MINING AND SCIENTIFIC PRESS by A. D. GASSAWAY, E. M.

The Magalia drift mine, commonly known as the Perschbaker, lies under the lava capping of the Magalia ridge, at an average elevation of about 2000 feet, between Big Butte and Little Butte creeks, in sections 13 and 24, township 23 north, range 3 east, M. D. M., Butte Co., California.

The channel was first discovered on the west bank of Little Butte creek and followed down stream under the capping of tufa and volcanic mud 3000 feet, on an average grade of about 11%.

The course and grade of the channel were very irregular and as the work progressed the water increased until there was about 35 miner's inches to contend with.

The plant consisted of three boilers and two small air compressors at the mouth of the mine on Little Butte creek, and a steam hoist and line of steam pumps underground, which rendered the mine a very expensive one to work; the plant becoming inadequate, the mine was temporarily closed down, and finally passed into the hands of N. D. Rideout and J. B. Haggin who resumed operations in the spring of '94.

As the topographical features of the surrounding country rendered it impracticable to tap the channel with a deep drain tunnel, a perpendicular shaft was sunk 512 feet deep to bedrock, about 45 feet ahead of the face of the old workings. The shaft is double compartment, the inside dimensions are 5x11½ feet. The hoisting and pumping compartments are 5x4½ feet and 5x6 feet respectively. The timber sets are placed 5 feet apart from center to center and are made of 8x8-inch sawed spruce, lagged by 2x8-inch plank of the same material.

At first the shaft cut through a stratification of volcanic ash and lava to a depth of 146.5 feet, when a stratum of basaltic sand and gravel about 6.5 feet thick appeared with a slight increase in the flow of water which had been small to this point. Seventy-two feet more of volcanic material were then passed through, when another stratum of basaltic sand and gravel 20 feet in depth was encountered.

The flow of water now increased from 35 gallons to 165 gallons per minute and sinking was temporarily stopped. In sinking the first 200 feet the work was done by means of a portable boiler and steam engine, 8x12-inch cylinder, and a 6-inch jackhead pump. Meanwhile a plant, consisting of two boilers, hydraulic hoist and air compressor was installed.

A large compound differential plunger sinking pump, weighing about eight tons, was then suspended in the shaft by blocks and a ⅝-inch steel cable and operated by steam-heated compressed air. The diameters of the high pressure and low pressure cylinders were 10½ inches and 18 inches respectively. The diameters of the plungers were 10 inches and 14 inches respectively and the length of the stroke 24 inches.

Near the 245-foot level a fissure, or water course, in the lava was cut and the flow of water increased to nearly 500 gallons per minute. This fissure was followed through the lava to the 320-foot level, where it departed from the line of the shaft. Pump stations were cut at the 245-foot and 320-foot levels, the average flow of water between those points being 500 gallons, or about 44.5 miners' inches. Part of the time it amounted to 625 gallons per minute, or about 56.6 miners' inches.

One of the greatest difficulties to contend with was the volcanic sand and grit, which cut the pumps out and interfered with the work to such an extent that it was finally necessary to attach a separator, or settling chamber, to the lower part of the pump between the latter and the suction hose. The separator was so constructed that the water on entering the chamber was deflected from a perpendicular to a horizontal course and caused to assume a rotary motion against the walls of the chamber, whence it would drop to the bottom. When necessary, the pump was stopped and the sand removed through an outlet made for that purpose. In order to carry on the work rapidly, two No. 7 steam pumps were used part of the time, in addition to the large pump described above.

The shaft continued on through lava to the 337-foot point, when another stratum, 10 feet in thickness and somewhat similar to the gravel encountered before, but finer, was cut through.

The next 65 feet was through a stratified formation of volcanic mud or ash. Fair headway was made through this material, as it was good blasting ground and the flow of water such that one of the No. 7 pumps handled it with ease, while the large sinker remained at the 320-foot level.

At 412 feet the shaft entered a stratum of cemented volcanic mud or ash 40 feet in depth. On passing through this, a 5-foot stratum of sand and gravel was entered, so loose that it was necessary to drive the lagging ahead to hold it. This stratum contained so much water that the large sinker was lowered to handle it, a duplex steam pump, size 12x8½x10 inches, replacing it at the 320-foot station to lift the water to the 245-foot level, where a compound duplex Dow plunger pump, size 10x16x8½x12 inches, raised it to the surface.

The next 50 feet was through the hard gravel of the channel resting on the slate bedrock.

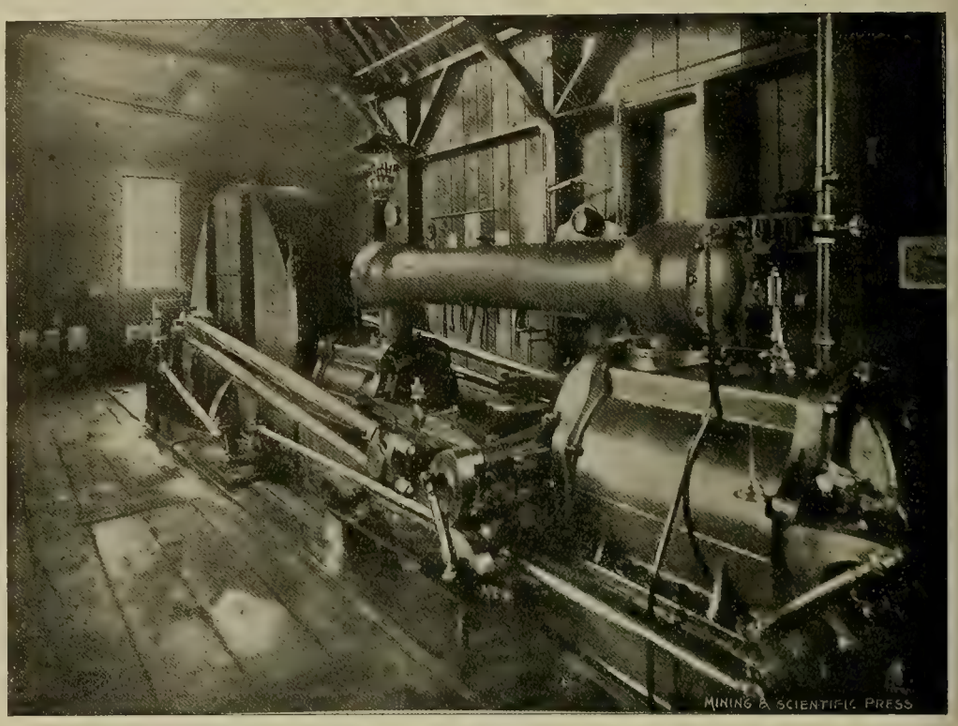
A large pump station and a sump 10 feet deep were then cut out in the solid bedrock at the bottom of the shaft. Here a large compound duplex plunger pump, size 16x26x8¾x18 inches, was installed. This pump weighs about 31,000 pounds and has a capacity of 500 gallons per minute when working under a lift of 500 feet vertical, and is driven by compressed air reheated by steam.

Steps were then taken to tap the old works, which were about 40 feet distant, and nearly full of water with a vertical head of about 200 feet. This was done by feeling ahead with long drills through the hard gravel—a necessary proceeding—as the position of the old face was not exactly known. On June 14, '96, a 10½-foot drill hole broke through and the water was gradually drawn off in a few days, the large pump and a relay system, composed of the large sinker suspended at the bottom of the shaft, and the pumps at the 320-foot and 245-foot levels throwing the water to the surface—a distance of 510 feet. At one time these pumps acting together threw 80 miners' inches of water to that point.

The Channel.—The channel has been followed down stream from the shaft about 3950 feet. The first 1750 feet has an average grade of about 6%. At that point a fault with an upward throw of about 5 feet was encountered. The next 1450 feet, reaching to a point 3200 feet from the shaft, has an average grade of about 4%. Here a second fault was encountered. This one has an upward throw of about 38 feet on an angle of inclination of 58°, with a course S. 30° W., perpendicular to the line of strike, which was S. 60° E. (magnetic). Before reaching the fault the grade of the channel becomes lighter, 2% or 3%, and sand banks and bars were numerous. There was a clean cut of the channel and the faulted section was found about 32 feet above its normal position and 10 feet to the westward. The movement of the fault on the upstream side occurred in serpentine bedrock, the groovings or striations being very prominent at some points, while at others the bedrock faces were as smooth as glass. The gravel of the channel was broken and fissured in the immediate vicinity of the movement.

The grade of the faulted section of the channel has been changed, it being comparatively level to the 3450-foot point, where a third faulting occurred with an upward throw of about 6 feet, the movement and strike being parallel with that of the other two. The movement here also occurred in serpentine. The grade from this point to the face, about 500 feet, is about 3%, the indication being that it will increase.

The bedrock of the faulted section is composed of successive belts of serpentine, eruptive rock, slate and porphyry, with a few small veins of asbestos lying in the serpentine. The eruptive rock is very hard and the belts vary in strike and dip. The contact of these formations is very smooth and prominent. The downstream side of the third fault has not yet been reached, so the extent of the raised section is unknown. Beyond, the channel may lie in



AIR COMPRESSOR, MAGALIA MINE, BUTTE CO., CAL.

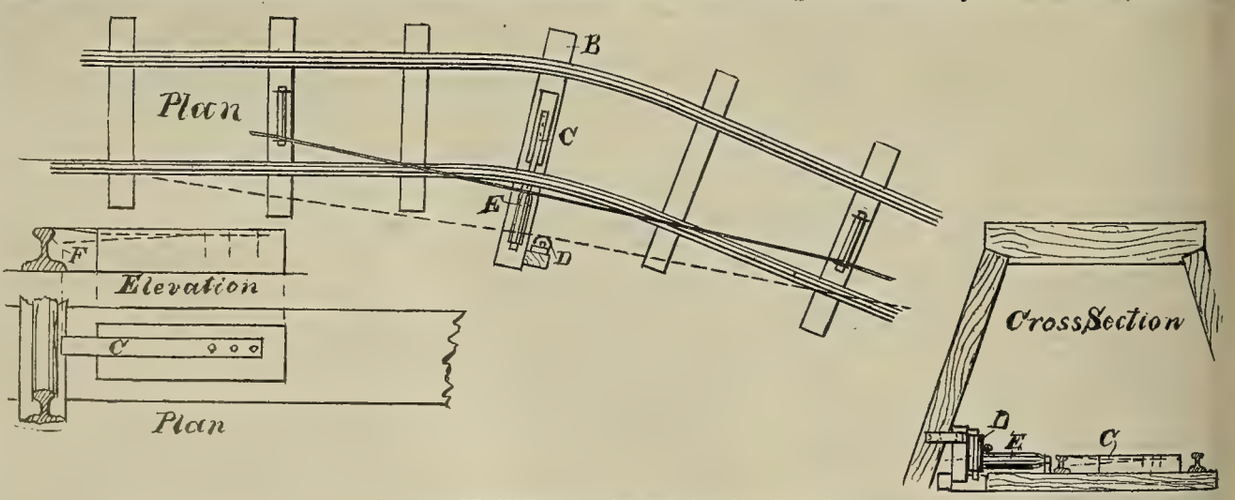


FIG. 1.—ARRANGEMENT OF TRACK ON CURVE.

C is an enlarged view of the spring which is depressed to *F* when the wheel passes.

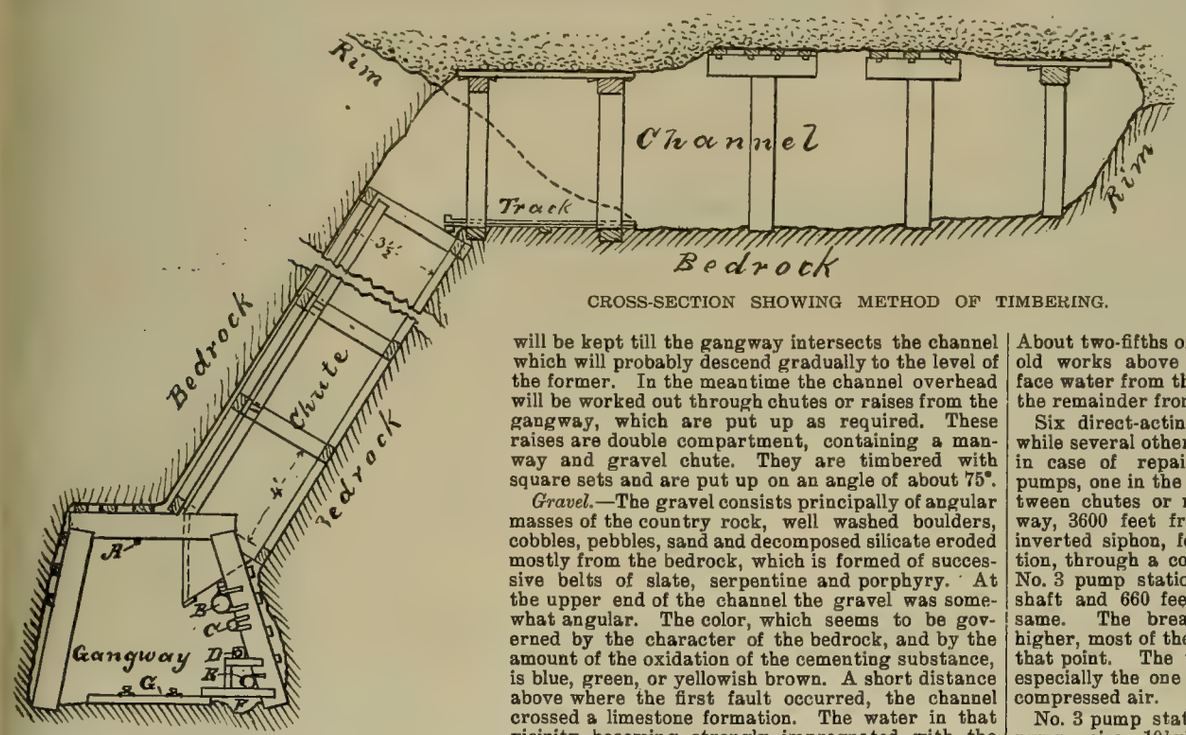
its normal position. Faultings are somewhat uncommon in this locality, although they are numerous in northern Sierra and Plumas counties. In southern Sierra and Nevada counties the grades of the ancient channels have not been altered greatly by these movements; but some portions of Placer county show such action, there being a prominent fault exposed in an old hydraulic pit near Yankee Jim's.

Methods of Working.—The channel is narrow and tortuous, with rims somewhat abrupt. The breast seldom exceeds 60 feet in width. The gangway is kept in or near the trough of the channel, in order to drain the ground and handle the gravel to the greatest advantage. As a result, the gangway is very crooked, making the haulage somewhat difficult on account of the many irregular curves in the track. The track has an 18-inch gauge, and is made of steel rails, twelve pounds to the yard. The empty trains, consisting of three cars, with a capacity of 16 cubic feet each, run down by gravity. An underground hoist is located near the bottom of the shaft, and another at the 1750-foot station. The first is run by either steam or compressed air, the second by compressed air. On account of friction and the weight of the cable, the trains will not run down beyond the second hoist, where the grade becomes lighter. A 1½-inch crucible steel rope, seven wires to the strand, is used on the upper hoist. A cable of this character, although not so flexible, wears better than a rope composed of nineteen wires to the strand.

A turnout or switch has been constructed at the 1750-foot station near No. 2 hoist, where the trains pass each other. As the average grade below is somewhat less than 3½%, a ⅝-inch plow steel rope is used to lessen the friction and weight as much as possible. Four cars to the train are used on this section, one of them acting as a dummy to increase the weight of the train, remaining on this division, the switching being done at No. 2 hoist. The trains on this division run down 1800 feet, or 3550 feet from the bottom of the shaft. The track in this portion of the mine is straighter and the grade more uniform than above.

The rope is carried around the curves on a system of horizontal and perpendicular rollers placed in the center on the outside of the track. If located outside, a spring is placed between the rails to throw the cable over the rail onto the roller to lessen the friction and to save the rope, as shown in the sketch, Fig. 1. These rollers are made of wrought iron tubing 2 to 4 inches in diameter, cut to the proper length, usually 8 to 12 inches, and are fitted with hard wood turned down to the proper size in the lathe. They are all made at the mine with the exception of the cast iron boxes for the upright rollers, which are purchased in lots ready for use. There are about 500 of these rollers in the mine.

When the second fault was encountered the gangway was carried ahead beneath the channel in bedrock on a 2½% grade to station No. 3 which is 3625 feet from the shaft, and as far as gravity will carry the trains of the second division. Another turnout was constructed here, and the gangway carried a head on an upgrade of ¾ of an inch to the rod. This grade will be kept till the gangway intersects the channel which will probably descend gradually to the level of the former. In the meantime the channel overhead will be worked out through chutes or raises from the gangway, which are put up as required. These raises are double compartment, containing a manway and gravel chute. They are timbered with square sets and are put up on an angle of about 75°.



CROSS-SECTION SHOWING METHOD OF TIMBERING.

FIG. 2.—MAIN GANGWAY IN BEDROCK, CHANNEL OVERHEAD.

Gravel.—The gravel consists principally of angular masses of the country rock, well washed boulders, cobbles, pebbles, sand and decomposed silicate eroded mostly from the bedrock, which is formed of successive belts of slate, serpentine and porphyry. At the upper end of the channel the gravel was somewhat angular. The color, which seems to be governed by the character of the bedrock, and by the amount of the oxidation of the cementing substance, is blue, green, or yellowish brown. A short distance above where the first fault occurred, the channel crossed a limestone formation. The water in that vicinity becoming strongly impregnated with the carbonate of lime, on circulating through the gravels below redeposited the lime in solution. This precipitated lime cemented the gravel down to the second fault, some of it becoming very hard. The most heavily cemented portions occurred in the low depressions of the channel, while other portions were comparatively free from the cementing substance. Below the second fault the gravel is not so heavily cemented although it is quite hard.

Drills.—Nearly all of the drilling is done by machines driven by compressed air, one 3-inch Leyner and two 3-inch Ingersoll-Sergeant drills being used for that purpose. It is much more profitable to breast with machines than with moils or hand drills as the holes are deeper and break better. Experience shows that a hole can be put in gravel as well with a machine as by hand. Single screw drill columns from 3 to 6 feet in length are used mostly, although the double screw column with arm and clamp is sometimes used in the gangway. The breasting is carried as low as good work will warrant, most of the gold lying on or near the bedrock. No. 2, 30%, Hercules powder is used for breasting and in the soft rock of the gangway. Some of the eruptive dykes in the latter are so hard that they require No. 1 or 70%.

Timbering.—On an average the ground is not heavy and the greater part of the timbering is done with a single post and cap, lagged overhead and securely wedged, the intention being to keep the ground from starting. The caps are approximately 8x10x36 inches long trued up on the top and bottom, and are made of round or split timber. The posts are made of round timber with an average diameter of 12 inches. The length is governed by the height of the breast.

The gangway is timbered with tunnel sets consisting of two 7-foot posts and a cap 4½ feet in the clear. These sets are placed 5 feet apart from center to center and securely lagged overhead, 5½-foot lagging, 2 inches thick and not less than 6 inches wide, being used for this purpose. For breasting, 3½ and 4-foot lagging, 2 inches thick and about 6 inches wide, is used. There is no "swelling bedrock" in the mine, and the roof is generally hard or cemented. The sketches show the methods of timbering. (See Figs. 2 and 3.)

Signal Bells.—For making signals from the bottom of the shaft to the surface the ordinary bell wire and gong are used; but below that point electric gongs, 8 or 12 inches in diameter, are employed. No. 12 rubber covered Habershaw copper wire is used on porcelain insulators. The battery consists of about one-half dozen Hercules cells. They cost but little and do good work. Push buttons were used at first, but they soon got out of order on account of the dampness. Now the circuit is closed by bringing the bare ends of the wire in contact with each other. The bell wires were not serviceable on long distances on account of the slack in the wire and friction.

Drainage.—The mine is making about 40 inches of water at present, somewhat less than about a year ago. This is probably owing to the comparatively dry season. About two-fifths of this amount is coming from the old works above the shaft, a small amount of surface water from the 70-foot level in the shaft, and the remainder from the new works.

Six direct-acting pumps are steadily employed, while several others are held in reserve, to be used in case of repairs or breakdown. Two No. 7 pumps, one in the breast to overcome the grade between chutes or raises, and the other in the gangway, 3600 feet from the shaft, together with an inverted siphon, force the water to No. 3 pump station, through a column composed of 5-inch casing. No. 3 pump station is 2950 feet distant from the shaft and 660 feet vertical below the collar of the same. The breast at present being somewhat higher, most of the water from there is siphoned to that point. The two pumps have very little to do, especially the one in the gangway, and are run by compressed air.

No. 3 pump station contains a compound duplex pump, size 10½x16x8½x10 inches. In the same station is a No. 8, which is used in case of an emergency. These pumps throw the water to a point near the large pump station at the bottom of the shaft through about 2800 feet of 6-inch casing and have a lift of about 150 feet. They are run by compressed air reheated by steam, and may be run by steam alone. They are, also, arranged to pump through to No. 2 pump station, 1150 feet distant and 1800 feet from the shaft.

No. 2 pump station contains a compound duplex pump, size 6x12x8½x10 inches, and also a No. 7, to be used in case of repairs on the other. These pumps handle the drainage of the the mine from the shaft to this point, and, in case of an emergency, relieve the pumps in No. 3 station.

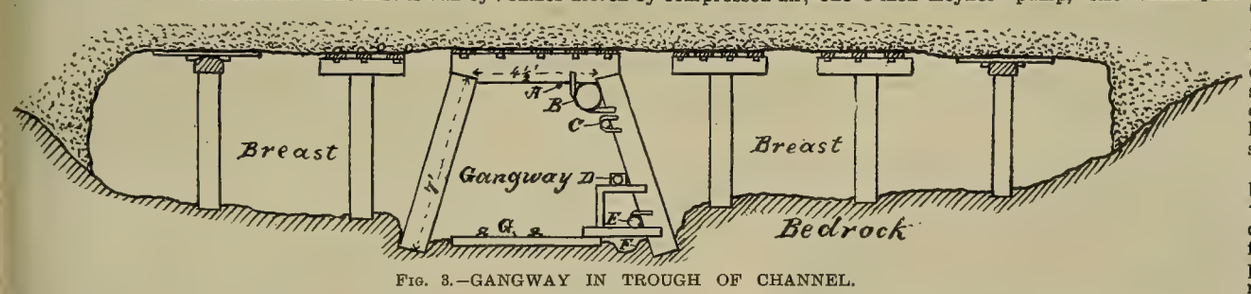


FIG. 3.—GANGWAY IN TROUGH OF CHANNEL.

A shows position of electric bell wires; *B*, 10-inch air pipe; *C*, compressed air pipe; *D*, boxed steam pipe; *E*, position of pump column; *F*, drain; *G*, track.

The pump station at the bottom of this shaft contains the large compound duplex plunger pump, before described, with a capacity of 500 gallons per minute under a vertical lift of 500 feet. On the same station is the compound duplex Dow plunger pump, formerly at the 245-foot station, and now used to relieve the other when the latter is undergoing repairs. These pumps are arranged to run either by compressed air or steam. At the 320-foot station are two No. 8 pumps, and at the 245-foot level is a large pump, size 16x10x16 inches. These pumps, with the large sinker suspended at the bottom of the shaft, form a relay which in an emergency can be used to assist the other large one. At the 70-foot level is a small Dow pump, which throws out the surface water that accumulates there.

Compressor.—The compressor is of the compound type, built by the Norwalk Iron Works of Connecticut. The diameters of the intake and compressing cylinders are 26 inches and 17½ inches, respectively, with a 30-inch stroke. It is built to run at ninety revolutions per minute and maintains an average pressure of about ninety pounds. It has a nominal H. P. of 215 and a capacity of 1659 cubic feet of air per minute at the level of the sea. The machine is driven direct by a 126-inch Pelton wheel, made heavy enough to act as a fly wheel, running under a vertical head of 160 feet. Two nozzles of about 4¼ inches and 4½ inches diameter, respectively, direct about 655 inches of water on the wheel.

(*To be Continued*)

The Rights of Tunnel Claimants.

Following is a full text of a decision given Jan. 16, '99, by Judge Hallett in a Cripple Creek case—the Matoa Gold Mining Company vs. the Chicago-Cripple Creek Gold Mining Co.—in which the defendant corporation took from a patented claim a large amount of ore by virtue of an alleged right obtaining from a certain tunnel location, the bore of which passed through the ore body in question, which occurred within the limits of plaintiff's claim:

Instructions to Jury.—Hallett, J. (orally): These instructions are given on behalf of the plaintiff:

This is an action for damages by the plaintiff against the defendants on account of an alleged trespass, alleged to have been committed upon certain mining property of which the plaintiff claims to be the owner, situate in Cripple Creek mining district, El Paso county, Colorado. The plaintiff alleges that from on or about the 4th day of August, 1896, until the 1st day of January, 1898, it was the owner and entitled to the exclusive possession and enjoyment of certain premises described in the amended complaint;

That during said period of time the defendants unlawfully entered upon said premises in the underground workings thereof and took and carried away and converted to their own use a large amount of ore and mineral-bearing rocks of great value.

The defendant—the Chicago-Cripple Creek Gold Mining Company, L. E. King—deny such unlawful entry and the taking and carrying away of the ore, and further claim a right to enter upon said premises and take any ores found within the veins, lodes and ledges from which the same is alleged to have been taken by virtue of a tunnel location made and owned by the Chicago-Cripple Creek Gold Mining Company, known as the Chicago-Cripple Creek Gold Tunnel & Tunnel Site Company, and by virtue of certain tunnel lode claims located by the owner of the said tunnel site on vein or veins cut in the bore of said tunnel while passing through the premises in question.

The defendants—the Mutual Benefit & Leasing Company, John Nolon and W. W. Wemott—each filed a disclaimer in which they deny any title, claim or interest whatever in the premises on which the trespass is alleged to have been committed, but containing no denial of the trespass as alleged in plaintiff's complaint.

Upon these issues the court instructs you that the burden is upon the plaintiff to show its ownership of the ore in question; the court also instructs you that, if you find any ore was taken from the premises by the defendants as alleged in the complaint, and at the time of the taking of said ores the plaintiff was the owner of said premises, then it would be entitled to recover the value of the ores so taken, which is to be determined by you under the rules hereinafter stated.

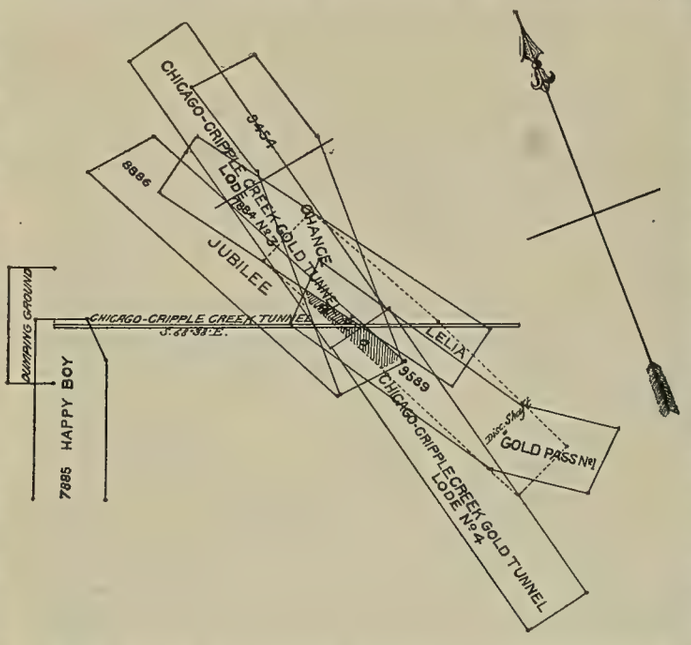
It appears from the evidence, and for the purposes of this case is undisputed, that on or about the 12th day of November, 1891, James H. Freeman, Jr., Jesse B. Petersen and William F. Petersen entered upon the unappropriated public domain of the United States and discovered and located the Gold Pass No. 1 lode mining claim, and that this location included within the surface lines the tract of ground upon which the alleged trespass, if any, was committed;

That subsequently thereto and on the 10th day of June, 1895, an amended location certificate of said claim was filed for record in the office of the County Clerk and Recorder of the county of El Paso, State of Colorado, and that the said Gold Pass No. 1 location was transferred by divers mesne conveyances from the locators thereof to the plaintiffs in this case and United States patent for the said Gold Pass No. 1, issued on the 15th day of April, 1898, to the plaintiff in this action.

It further appears in the evidence that on the 28th day of June, 1892, the defendant—the Chicago-Cripple Creek Gold Mining Company—located a tunnel and tunnel site three thousand feet in length from the mouth or portal to the terminus thereof, and that the line and bore of said tunnel as projected in said location intersects and crosses the tract of ground included in the original Gold Pass No. 1 location and the portion of the tract of ground described in the plaintiff's complaint and upon which the alleged trespass, if any, was committed; that subsequently and about the 20th day of December, 1896, while driving the bore of said tunnel through the premises included within Gold Pass No. 1 location, defendants cut a certain vein or veins of mineral-bearing rock and attempted to locate thereon two tunnel lode claim locations, numbered respectively 3 and 4—one extending northerly from the bore of said tunnel approximately fifteen hundred feet and one southerly also a distance approximately of fifteen hundred feet.

And it further appears that the ore in controversy in this case was taken from the vein or veins so attempted to be located by the aforesaid defendants.

It further appears in evidence that on or about February 8, 1894, Edward R. Warren made a location known as the Jubilee lode mining claim, which overlapped a portion of the Gold Pass No. 1 mining claim and included within its surface limits a part of the territory upon which the alleged trespass in this case was committed; that the owners of the Jubilee location subsequently deeded to the owners of the Gold Pass No. 1 location the tract of ground last above referred to, and thereupon the owners of the Jubilee location proceeded to patent, and the owners of the Gold Pass No. 1 location excluded from its application for patent the tract of ground so previously deeded to it, and it was subsequently patented to the owners of the Jubilee claim and excluded from the patent of the owners of the Gold Pass No. 1 claim.



PLAT OF CLAIMS IN CONFLICT IN MATOA vs. CHICAGO-CRIPPLE CREEK CASE.

You are instructed that a valid location of a lode mining claim entitles the owner or owners thereof to the exclusive possession and enjoyment of all veins, lodes and ledges the tops or apexes of which lie within the surface lines of such location, or whether appearing at the surface or between vertical planes extending downward to the full depth, and that this right of exclusive possession and enjoyment applies not only to the vein upon which the discovery and location is made, but to all veins within the surface limits as herein stated.

The Gold Pass No. 1 location having passed to patent, is presumed in this case to have been in every respect regular and valid, entitling its owners to the exclusive possession and enjoyment of all veins, lodes and ledges the tops or apexes of which lay within its surface boundaries whether appearing at the surface or at any point within vertical planes extended downward through the full depth, and that they were entitled to such rights at the time the tunnel location of the defendant was made, such lode claim location completely segregating the tract of ground included within its boundary from the public domain; and therefore the defendant acquired no rights by its attempted location of a tunnel site across and through said tract of ground included within the Gold Pass No. 1 location, because such territory was at that time no part of the public domain of the United States, and was not subject to location under any law of the United States.

The Court instructs the jury that the ground in which it is charged the trespass occurred was included within the lines of the Gold Pass No. 1 lode, as originally located, and that the owners of the same, by taking a deed from the owners of the Jubilee for a part of such ground in conflict between the said two claims before its exclusion from the Gold Pass No. 1 lode and its subsequent patenting to the owners of the Jubilee lode, was not a waiver of the priorities which it had as a part of the original Gold Pass No. 1 location.

The Court instructs the jury that, if they believe from the evidence that the defendants committed the trespass charged and extracted ore belonging to the plaintiff, in fixing the amount of the plaintiff's damage they cannot allow the defendants anything in the way of credit for mining the ore or taking it to the surface, but that the amount of damages which they must find for the plaintiff in that case is the value of the ore at the mouth of the pit; or, in this case, the mouth of the tunnel or other openings through which it was mined.

The jury are instructed that the plaintiff company having charged a trespass against the defendants, the burden of proof is upon it to show that the same was committed by the defendants and the amount and value of the ore extracted by them with as much certainty as the circumstances of the case will permit. The jury are further instructed in this connection that, where one person wrongfully enters the property of another, and not only commits an injury thereto, but takes away the means of proving with certainty the nature of the loss, the law does not require the one whose property has been damaged to make more than a reasonable showing of the extent of the same, but requires the one committing the trespass after such has been made to bear the full responsibility of the uncertainty and confusion which he himself has produced and to make a full and complete showing of all of the facts, showing the amount of the damage he has inflicted; and if the jury believe from the evidence that the defendants in this case have not produced the full record of all of the sales of ore extracted from the property in controversy, and testified fully as to each and every shipment of ores made therefrom, the value of the same and the amount received therefor, then and in that case the jury are at liberty to fix the amount of the ore and the value of the same extracted, from the testimony of the plaintiff herein, taking into consideration for so doing the total number of tons shown to have been extracted and the average value of the same as shown by shipment or in any other manner.

The Court instructs the jury that, if they believe from the evidence that any or all of the defendants committed the trespass and extracted the ores charged against them in this case, under and by virtue of any understanding or agreement between them so to do, then they are joint wrong-doers and the jury may find against any or all of such defendants. On the part of the defendants this instruction is given:

You are hereby instructed that the plaintiff herein cannot recover in this action for the mining and extracting or selling of any ore in the upraise or winze appearing upon the maps, if without the territory described as a certain portion of ground adjoining the Gold Pass No. 1 lode mining claim containing .432 of an acre and marked upon the map, plaintiff's exhibit, in green or any other part of the claim without such tract.

Given January 16, 1899.

Good Record in Sinking the Central Eureka, Cal., Shaft.

TO THE EDITOR:—The report that we were sinking the shaft of the Central Eureka mine at the rate of 50 feet per week was a little misleading. It is true we have sunk and completed 15 feet of shaft in two days, but our regular work is 5 feet per day. In order to do this, every man must be proficient in his business and work with all the strength and energy that is in him. All work is done by contract; and if the contractors complete 100 feet of shaft inside of thirty days, they receive $100 premium. I have tried this several times with different crews of men, and it always proved a success.

All the conditions in this mine are favorable for rapid sinking. The shaft is sunk in the fissure, which is gouge and crushed, foliated slate. The ledge is in the contact, and the hanging wall, which is smooth and hard, forms the east side of the shaft and needs no spiling, the ends and footwall being lagged.

The shaft is 5′x10′ in the clear and divided into three compartments; 12″x12″ Oregon pine is used in timbering the shaft, and for skip tracks we use 4″x12″ with 2″x4″ scantling nailed on top, and on that ⅝″x2½″ track iron. Ladders are made of 2″x4″, with ¾″ iron rounds. An 11″ air pipe is also carried down.

The contractors do all labor, putting in all timbers, tracks, ladders and air pipes, sinking and making a complete shaft for $8 per foot; they pay for all powder, fuse, caps and candles. There are nine men on the contract and all share alike, working three on a shift in eight-hour shifts. All the ground is blasted, though some of it could be picked; but it is cheaper and quicker to blast it. There is very little water to contend with, most all being sent up with the dirt.

The strike made in the shaft at the 1160-foot level was about as reported in the Amador *Record*. The shaft is being sunk alongside the ore body; and, until a station is cut and drifts run, nothing will fully determine how extensive this ore body is. The shaft is now 1260 feet deep. WM. R. THOMAS,

Sutter Creek, Cal., March 29th, '99. Supt.

Experiences of a Working Miner.

NUMBER IX.

Written for the MINING AND SCIENTIFIC PRESS.

When Mr. K—— was general manager of the W—— mine it was almost all a man's life was worth to apply for a job. Every stranger was looked upon with suspicion. Not knowing of this, and paying but little attention to the conspicuous signs about the premises—"Positively no Admittance," "Beware of the Dog," "Keep Out" and other cheerful legends of the sort—I struck Mr. K—— for a place. He looked me all over carefully and said, "What do you want to do?" "Want to work," was my reply. "Work at what?" came next.

"Well," I answered, "I would like to beat a drill—at least that's what I came here for; but if you have anything better than that I am ready for it."

"Know anything about a mill?" he inquired.

"Oh, yes," said I, "I know all about running quartz mills."

"Do, hey? Well, I don't want you."

This was certainly not encouraging and beyond my understanding, so I said "Why not?"

"Don't want fellows around who know so much," said he, in a most positive manner.

"You surely don't want men around who do not know anything," I ventured.

"No," said he, "not exactly that. I need men who know enough to learn something, but who don't know it all."

"I want to work," I replied, "and I can be the worst numbskull you ever saw, if necessary. I heard you had a process at this mill which is out of the ordinary, but I didn't come here to work in the mill, but in hope of getting a job in the mine."

"Yes," he answered, "my process is secret and I don't dare to have it patented, for that would give the whole business away."

"That's so," I said, confidentially. "What is the particular advantage of your process—high extraction, I suppose, and cheapness?"

"Yes, sir," he replied, "you have hit it exactly. It's dirt cheap as a process, and would you believe it I extract a higher percentage than the assay."

"Great Scott!" I exclaimed in feigned wonder. "Is that possible. I have heard of such processes, but never came across one myself before. Why don't you have it patented and sell the right to use it on a royalty. It would bring you an immense income."

"Yes, I know," he answered thoughtfully, "but you can't trust them—you can't trust them."

I didn't stay at the W—— mine, but the natural result followed after spending considerable money: the financial backers of the concern got tired of this secret process business and quit. To-day the ore of this mine is being worked by a well-known process and paying, but Mr. K—— is not manager. A somewhat similar case came to my notice two or three years ago at P——, where a mill was built to work ore running up into the hundreds of dollars per ton. The mine was closely guarded and no one was permitted to enter. The mill was a marvelous aggregation of furnaces, kettles and rolls, the purpose of which could only be guessed at. Numerous reputable assayers had tested the "ore" from this mine, but none of them could get anything out of it. The metallurgist of the mine, however, showed numerous buttons—big ones, too, but he had a "secret flux" that did the business. It is scarcely necessary to say the gold had been previously introduced in the flux and the alleged ore contained no gold at all. It has been my experience that these fellows who have secret processes which "return more than the assay," and assayers who use "secret flux," are universally fakirs who have nothing of value, and use this scheme to dupe moneyed people. It is not a hard matter to form a "trust" on commercial commodities, but rather difficult to secure and hold a "corner" on knowledge. Sometimes these concerns, which are conducted on such conservative lines that the "No Admittance" sign is in evidence all over the place, have back of it a fear of criticism rather than that some visitor may learn secrets which may prove to his advantage elsewhere.

One of the secrets of successful mining is the ability of the manager to see into the future and anticipate the requirements of his mine. The G—— mine was worked for some years and produced a large sum of money. The flow of the golden stream seemed without limit, and the owners spent money lavishly everywhere, except at the mine. In time the mine got too deep for the hoisting plant, and the volume of water increased with the deepening of the shaft and the extension of the levels. At length it was apparent something must be done to take care of the water; so the old pumps were fixed up as well as their age and condition would permit. New pumps were needed, and a new engine would be required to run them, and this would cost several thousand dollars, and money for the purpose could not be spared. The ground was heavy and the deep shaft needed repairing; but to stop all other work and cut off the bullion supply was suicidal. There was no immediate danger of complete collapse, anyhow; so the bucket was reduced in size to clear the settling timbers, and things still went well. In a month or two it could plainly be seen that the timbers were pressing closer to the bucket; so a bucket of still smaller diameter and greater length was put in and all again went well, though this latter change made it a little inconvenient in loading such a tall bucket; but tall miners were hired who could reach it, and the mine still worked. The timbers crept closer day by day, until, it being no longer practicable to reduce the size of the bucket, some of the most threatening timbers were cut out sufficiently to let the bucket pass; but an end came to that, also. The pumps gave trouble again, and soon the expense was greater than the income. The weak treasury was unable to stand the pressure, and the mine was shut down and remained closed for years. It was again opened through a new shaft, the vein was developed under the old workings, and it is a larger and more profitable mine to-day than at any time under the old management. There are several ways of handling a mine, and you are at liberty to choose which of these ways is the better.

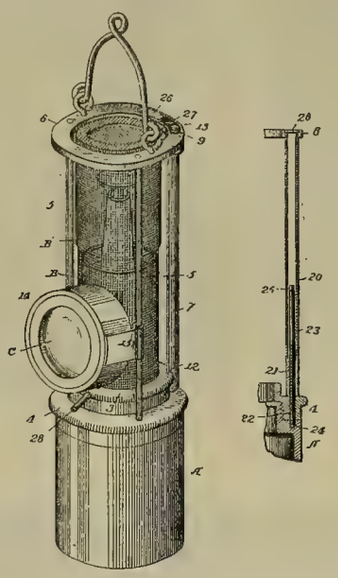
Not long ago I ran across the president of a mining company who told me he was paying a mill man a large salary for saving the gold in his sulphurets. He said, in answer to several questions, that amalgamation only was the treatment to which the ore was subjected, and that the mill contained, beside the power, only stamps and plates. Then he showed me the ore, and insisted that it was a fair sample of all of his ore, and there was not a single speck of sulphuret in any of it—a white, rather porous quartz, containing a little iron oxide, but absolutely no pyrite or other sulphide mineral, and remarkably free milling. This is simply another class of fakir, who wants something for nothing. MINER.

Latest Mining and Metallurgical Patents.

Patents Issued March 28, 1899.

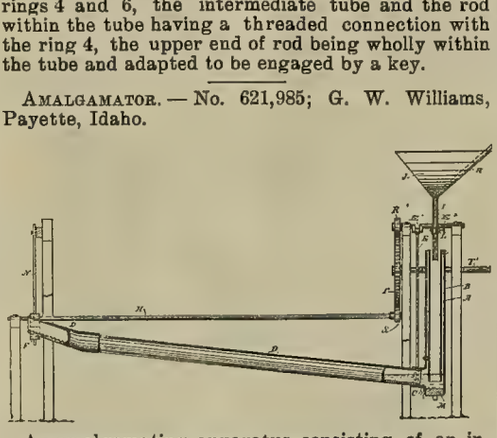
Specially Prepared for the MINING AND SCIENTIFIC PRESS.

MINER'S LAMP.—No. 622,076; H. J. Richards, Wilkesbarre, Pa.



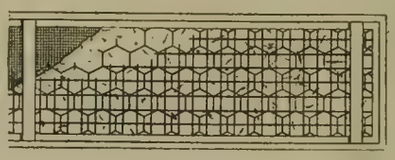
In a safety lamp, the combination with the oil cup and the gauze tube, of the ring 3 to which the tube is connected, the ring being provided with a notch 12, the ring 4 between the ring 3 and the oil cup, the tube engaging the notch 12 and resting on the ring 4 and the locking rod within the tube, the rod having a threaded portion engaging the ring 4 and an extension engaging a socket in the oil cup; also the combination with the oil cup and gauze tube of the rings 4 and 6, the intermediate tube and the rod within the tube having a threaded connection with the ring 4, the upper end of rod being wholly within the tube and adapted to be engaged by a key.

AMALGAMATOR.—No. 621,985; G. W. Williams, Payette, Idaho.



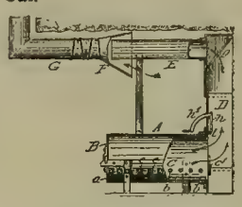
An amalgamating apparatus consisting of an inclined suspended pipe, containing mercury, means for giving a vertical motion to one end of it, a simultaneous horizontal motion to the opposite end, means for delivering the material to be acted on into the lower and receiving end of the pipe, it having its discharge end inclined upwardly to a greater degree than the general inclination of the pipe, a vertical feed pipe connecting with receiving end, a hopper or tank from which the feed pipe leads, and a water pipe discharging into the tank to agitate the contents to prevent packing.

CONCENTRATOR.—No. 621,986; G. W. Williams, Payette, Idaho.



A concentrator consisting of a sluice of essentially upright sides, eider-down cloth superposed upon blanket material and fixed to form a bottom for it, a second narrower sluice of similar form adapted to fit within the outer one, a bottom therefor formed of superposed screens of different mesh, and side strips beneath whereby the screens are raised above the fibrous surface of the outer bottom and an intermediate underflow is formed.

THAWING APPARATUS.—No. 622,053; J. W. Livermore, Selma, Cal.



In a thawing apparatus, the combination with a furnace of a heating chamber having a closed back, an opening in the back communicating with the furnace, a hinge connection between the furnace and chamber, whereby the chamber can be adjusted from vertical to horizontal and a hood to cover back opening when the chamber is horizontal, a perforated bar on one section, and a perforated guide on the other, the bar and guide being adapted to receive a pin for locking sections at any adjustment.

The Field of the Arrastra.

Written for the MINING AND SCIENTIFIC PRESS.

The old Mexican arrastra is looked upon as a rather slow machine for this age of progress and activity; but while admitting that the arrastra, as constructed and run by the Mexicans, who introduced it into this country, is a slow affair, the modern arrastra has a legitimate field of usefulness, and is by no means to be despised. On pages 32, 86 and 97 of the current volume of the MINING AND SCIENTIFIC PRESS are articles describing the construction and operation of arrastras, and that feature need not be discussed here. To secure the greatest efficiency in an arrastra, it should be run as an auxiliary to some type of crushing plant, either stamps or rolls, and the latter are probably preferable, as being somewhat lower in first cost for a given capacity. When ore has been crushed with rolls or stamps to, say, a maximum size of three-eighths or one-half inch, it is in good condition for the arrastra. If the ore is hard and flinty, it should be crushed still finer, say, to one-fourth inch at the maximum. When fed to the arrastra it crushes readily, when, on the same ore broken by hand to walnut size, the capacity of the arrastra is still quite small. The preliminary preparation of the ore by passing it through rolls increases the capacity of the arrastra greatly. By the employment of a screen sufficiently fine, the ore may be ground to an almost impalpable powder, but it is not advisable to grind it any finer than necessary to free the gold. By using water, steam or electricity for power, two good-sized arrastras in connection with five stamps or a set of rolls, with drags properly arranged so as to sweep the entire surface of the bed, will crush and properly amalgamate a larger amount of material than ten stamps, and do it cheaper and better. The arrastra is particularly useful in the treatment of ores in which the gold is "rusty," or covered with any film, as this coating is removed by the attrition of the drags, and the gold will then freely amalgamate. A third basin, provided with agitators instead of drags, would be found a desirable addition to such plant, as then the charge could be sluiced directly into the third basin, which occupies the same relation to the plant as the settlers do to a pan mill. The charges being drawn from the arrasta beds alternately, the cleaning up could be accomplished more quickly and satisfactorily in the settler, and the process becomes continuous. This arrangement is inexpensive, as the mine owner can build most of it himself.

A BICYCLE trust has been formed with a capital of $50,000,000, for the alleged purpose of reducing the cost of production, and not for raising the price on the wheels.

Placer and Quartz Gold Mining in San Miguel Co , Colorado.

The altitude of some placer mines would interest miners who get out gold only at altitudes varying from a few feet above sea level to 4000 or 5000 feet. In Colorado are placer mines worked at an altitude of over 10,000 feet. On this page is depicted the operation of two giants at Keystone placers on the San Miguel river in San Miguel county, Colorado. One would think that 10,000 feet above the sea a hydraulic miner could get dump enough without having to resort to the use of a hydraulic elevator, but one of those devices has been installed at the Keystone placers since the accompanying view was taken, for the use of which we are indebted to the courtesy of that enterprising newspaper, the *Journal*, published at Telluride, Colorado.

The San Miguel gold placer deposits are partly the results or fragments of former channels of that stream. Considerable work has been done, mostly by ground-sluicing. Unlike some of the big hydraulic mines of California, where an enormous amount must be expended before a dollar is produced, but which subsequently yield great returns, the San Miguel placers do not justify great expense in preliminary work. They are essentially "poor mar's diggins;" panning and rocking have been the principal means of getting out the gold; and while men have made fairly good wages that way, any attempt to work the bars on a big scale has not been financially satisfactory. San Miguel placer gold is rough and grainy; it runs about 30% silver and has a value of about $14 per ounce. In the vicinity of Telluride is being done a great deal of lode development, although deep snow interferes considerably ; in ordinary years work goes on continually. A view is presented herewith of the Butterfield mill, in Bridal Veil Basin, at an altitude of 11,000 feet, and also of the Gold King mill, Turkey Creek Basin, which has been steadily stamping out gold for eighteen years. At the Bessie mill, in Turkey Creek Basin, is found one of the most complete plants in southwestern Colorado. The process is one of roasting and amalgamating, the free milling ores of the San Miguel district being first treated in that way in the Bessie mill. The mill is 161x90 feet, 116 feet high. A 100 H. P. electric motor furnishes the power. The roaster daily capacity is 250 tons. The ore is handled automatically throughout. It passes into a 12x22 crusher, thence through a dryer, and through high-speed rolls, leaving them through a screen of ½-inch mesh; thence through a roaster, and then through another set of rolls, ground to a 20-mesh screen, and through another roll, which it leaves through a 40 to 60 mesh, thence to the mill, and over the amalgam plates. It goes from $7 to $10 on the plates. The cost of mining and milling is $1.02 per ton. Near Telluride, the metropolis of that region, is Pandora, a view of which is herewith given. In the background to the left is the mill of the Smuggler-Union. During 1898 there were treated in that mill 75,000 tons crude ore, from which was shipped 810 carloads of concentrates. Its capacity is over 200 tons per day. On the right of the picture is the building in which is the Kirby process for treating tailings. On the railroad track in the foreground is the engine room of the Meldrum Co., from whence compressed air is sent to drive the drills in the big tunnel beingrun in that vicinity.

THE GOLD KING MILL, TURKEY CREEK BASIN, SAN MIGUEL CO., COLO.

A surface tram runs from the mine in the distance to the mill in the foreground.

The Genesis of Petroleum and Asphaltum in California.

NUMBER X.

Written for the MINING AND SCIENTIFIC PRESS by A. S. COOPER.

Reservoirs for oil and asphaltum are created as follows: The porosity of limestone is created by chemical action, the changing of limestone into dolomite. The porosity of sandstone by the solvent action of water leaching out the cementing material, such as lime, silica, iron, etc. The capacity of shale for holding oil or bitumen by the mechanical bending and cracking of the strata, the cracks affording storage room.

Limestone.—The Trenton limestone is very productive under certain circumstances. In its normal condition it is a compact rock, and then it contains neither gas nor oil; but over large areas the limestone has been dolomitized and so transformed into a porous and cavernous rock, in which the gas and oil are contained.

The dolomitization of the Trenton limestone is probably occasioned by the removal of carbonate of lime by the solvent action of water charged with certain minerals, and as the Trenton limestone contains originally a small percentage of magnesia, it gradually becomes dolomitic in character, and, on account of its reduced bulk and crystallization, porous and cavernous.

When water has taken possession of shale in the shape of quarry water, or the shale is saturated with water, it is nearly impossible for oil to eject the water and enter the shale; the reverse is also true, when oil has taken possession of the shale it is nearly impossible for water to enter the shale. This is undoubtedly owing to capillary attraction of the fluids in the shale. When the surface of a capillary tube is greased it exerts but little capillary attraction upon the water, and when a capillary tube is moistened it exerts but little capillary attraction on oil. Other rocks act the same as shale, the finer the grain of the rock the greater the capillary attraction, and the more difficult it will be for oil to replace water or for water to replace oil.

Shale occupied by water makes a good encasement for oil and asphaltum.

The retention of petroleum and pissasphalt in the porous and seamed rocks cannot be affected without the accumulations or reservoirs having a cover or impervious encasement. This impervious encasement usually consists of unfractured shale, or other close-textured rocks, or porous and fractured rocks cemented and sealed with indurated bitumen or other minerals.

When the outcrop of bituminized sand is exposed to the atmosphere for a long time, the bitumen contained in it loses its volatile parts by evaporation and oxidation, turns brown and is easily pulverized between the fingers. The sand separates from the bitumen and the bitumen is easily ground to an impalpable powder. This brown asphaltum extends to but a short distance below the surface of the stratum. Beneath the brown coating of bituminized sand, the deposits receive a coating of hard asphaltum, made hard by evaporation and oxidation. The condition of the bitumen in the seamed and cracked shale resembles that which is in the sand. This concreted surface is impervious to the flow of pissasphalt and petroleum oil, and frequently sufficiently tight as to inclose natural gas. In fact, all porous or seamed rocks, when the base of the saturating petroleum is asphaltum, becomes water and petroleum-tight, by reason of the petroleum becoming concreted by oxidation and evaporation; the same as when a tree is wounded by a cut or puncture, the impissated sap soon closes the pores so that little sap escapes. The surface of the bituminized sands and shales is hard, increasing in fluidity as it enters the deposit or is removed from atmospheric influences.

In some deposits, a short distance from the surface will show a petroleum oil of 10° Beaume, decreasing at 1000 feet to 32° Beaume.

If rather stiff maltha is melted and poured into a hole in a sheet of iron $\frac{1}{16}$ of an inch in diameter, so that it will form a thickness $\frac{1}{16}$ of an inch on each side of the sheet, the sheet being $\frac{1}{16}$ of an inch thick, it cannot be removed with a pressure of water equal to fifty pounds to the square inch. The prodigious pressure necessary to force maltha through the interspaces of sand or irregular seams of shales for a distance of several hundred feet can hardly be imagined. In fact, the salvation of most of the accumulations of petroleum oil in California is owing to this induration of petroleum by oxidation and evaporation.

This impervious coating also protects the oil reservoirs from the entrance of surface water.

The petroleum oil in passing through the sand or shale collects the silt and carries it forward. This also assists in forming a cover, filling up the places through which the liquid hydrocarbons attempt to escape.

Under great pressure the petroleum oils are constantly alert to take possession of any space created by the uplifting or other movements of the earth, and if these oils are concreted into asphaltum by oxidation and evaporation they retain possession. The oil occupying the surface of the water in a formation has an advantageous position to perform this work, as the formation is more fractured in these parts than in the synclines and the dips of the anticlines.

The cut shows strata of bituminized sand on a ridge running north and south between the Coja creek and a branch of the Baldwin creek, seven miles west of Santa Cruz, California. The bituminized sand lies nearly horizontal and extends from canyon to canyon through the ridge. The dip of the shales and sandstones of the surrounding country shows that this is the apex of a large dome, covering an area of some twelve square miles. Overlying these strata of bituminized sand is a close-textured shale 40 feet thick and underlying the same is a porous and incoherent sand.

C. S. I. CO.'S BITUMINOUS ROCK MINE, SANTA CRUZ CO., CAL.

The Coja creek, lying immediately west of this deposit, is 200 feet deep and must have taken many thousands of years to form. Redwood trees, proving by their concentric circles to be several hundreds of years of age, are growing in the bottom of the creek. The impregnation of the sand with bitumen must have occurred before the gulch on either side of the deposit commenced to form through denudation, otherwise the liquid bitumen would have run out of the porous sand. From the horizontality of the surface of the porous sand which underlies the bituminous strata it must have been filled with water, forming a horizontal plane upon which the bitumen floated. This also must have occurred before the denudation of the gulch on either side. The petroleum must have been under considerable pressure, as it has thoroughly saturated the sand between the porous sand and the overlying shale, and where porous places have existed in the shale petroleum has been forced into them.

Notwithstanding the thousands of years which this bituminized strata has been exposed to the elements the bitumen in the interior parts of the deposit is at present liquid, its liquidity being preserved by the concretion of the bitumen on the top, bottom and sides of the deposit, stopping evaporation, oxidation and leakage. In these strata of sand, when bituminized, they contain gold in considerable quantity, whereas in those portions which are not bituminized but little gold exists. It would seem that the gold in the bituminized sand was protected from the solvent action of mineral water, the presence of the bitumen in the sand stopping the percolation of mineral water, whereas in the sands not bituminized this percolation is permitted and the gold is dissolved and carried away. But further examination will be required to be positive that such is the case.

Sand rock, sand and sandstone are composed mainly of rounded or broken grains of quartz of varying form, color and fineness. The material cementing the grains are either argillaceous, bituminous, silicious or calcareous, or a mixture of any of these four substances. Some of these sands contain cementing material, some in such a small quantity that they are friable. When found beneath the earth's surface they are seldom found in an incoherent state. When they are porous they are occupied by either natural gas, petroleum oil, or water (generally of a mineral character), or both of these fluids and gas.

The buoyancy of the oil in associated water is the force which impels the oil upwards. The oil is carried so far upwards that it sometimes escapes at the surface in the form of tar springs or seepages, and is lost, or it accumulates in porous or seamed strata beneath the surface of the earth. For the reception of the petroleum, oil or gas, the sandstone strata is at first made porous by the solvent power of water, which removes the calcareous and silicious cementing material.

(To be Continued.)

The Telluride Ores of the Black Hills of South Dakota.

Written for the MINING AND SCIENTIFIC PRESS.

In the northern Black Hills is an area covering several hundred square miles throughout which occurs gold ores of uniformly high grade, which, owing to their mineralogical characteristics, may be called telluride ores. They contain both gold and silver, and usually carry more than $20 per ton, and in some cases the value reaches hundreds of dollars per ton. These ores occur in shoots of varying size, from 30 to 200 feet wide, a few inches to 20 feet or more in thickness and often 800 to 2000 feet long. The ore shoots are bedded deposits, occurring in part as silicious impregnations, and in some instances the original rock (quartzite) is simply impregnated with the gold and silver and other accompanying minerals. They are found in the sedimentary rocks of the Cambrian, the lower deposits being in a quartzite, or lying immediately over it, forming the basal member of this series, which rests unconformably on the Archæan. The Cambrian has here a thickness of 250 to 300 feet and is succeeded upward by the limestones of the Carboniferous. There are two important beds of quartzite in the Cambrian and locally others of less importance. The telluride ores occur at several geological horizons, and in some localities there are two or more ore-bearing horizons. The limestones are also mineral-bearing, in them occurring two distinctly different classes of ore deposits: First, galena and iron sulphide ores, and, as secondary products of their alteration, lead carbonate and other lead minerals; limonite and, sparingly, hematite, with chloride of silver and gold. Second, flinty silicious concretionary masses carrying native gold; some of these ores are rich and are shipped to the smelters or other works for treatment.

These ore deposits are always associated with eruptive dykes, which without doubt furnished the channels along which mineral solutions from great depths reached the strata in which the ore shoots occur, and deposited by infiltration or impregnation the gold, silver and other minerals found in these ore deposits. They may be called contact deposits, as that is the form in which they are found, though it is doubtful that the overlying or underlying sheets of either sedimentary or eruptive rock had any considerable influence on the ore deposition. The formations in which these ore bodies occur were at one time a solid continuous sheet, covering the northern Black Hills and, possibly, the entire region, though there is a noticeable thinning out of the several beds southward, particularly in the western southern hills. Erosion has removed vast amounts of these sediments, and the areas are now separated, and some of them are, as islands, isolated from all others, and are merely remnants of the once continuous beds and are found capping hills and ridges. The sediments of the northern hills have been tilted, folded, crushed and faulted. The principal intrusives are rhyolite, trachite and phonolite. The latter appears to be associated with a number of the ore deposits, and as telluride ores are found associated with phonolite at Cripple Creek, all phonolite dykes are given close attention wherever found in these districts.

Terry's peak is the dominant mountain of the northern hills, though there are several other important peaks near it. These are Green mountain, Bald mountain and Sugar Loaf. In each of these mountains occur important ore deposits of the character above described. Terry's peak is an immense laccolite and has thrust sheets of eruptive rock into the sedimentary beds in all directions from the central mass, crushing, splitting and tilting the rocks of the Cambrian and sometimes separating them from the Archæan. Many other laccolites occur in this region, but no others on so large a scale. Several miles northwest of Terry's peak is Crow peak; a huge mass of sanidin trachite has thrust itself up through the sedimentary strata, but has only lifted the sediments, which are seen dipping away from the neucleal mass in all directions; but no evidence of laccolite can be observed, nor are there any later dykes cutting the formation, nor are there ore deposits in connection with this uplift.

A complete description of these ore deposits and their geological associations and the relation of the eruptives and their influence on ore deposition would be very interesting, though not more so, perhaps, than a brief history of the efforts made to success-

fully treat these telluride ores, which for years defied all attempts in that direction. No expense was spared, and the best and most skillful metallurgists of the time were employed, but for years all efforts were only partially successful.

The first discoveries of ore in this field were made in the earliest days of mining in the Black Hills—1876-'77—and the first mines of this class to attract attention were those of the Portland and Trojan groups on Green mountain. Numerous other discoveries were made later and a large amount of work done over a district not less than ten miles long by three miles wide, though the development of more recent years has greatly extended this area and it is very probable that it will be found that mines of the class described are co-extensive with the intrusion of the sediments by the eruptive dykes. Long after the discovery of the Green mountain mines, Ruby Basin, Golden Reward, Carbonate and Ragged Top were found. In the early days, however, lead carbonate and galena ores containing silver were mined, milled, smelted or shipped from the Galena district, and later the same thing was done at Carbonate; but at neither of these places was any attention given to the telluride ores, though these ores occur in both of the districts mentioned.

The first operations on a scale entitled to be called commercial were those of the Portland Mining Co., whose property is located on Green mountain. The development of this mine exposed a large amount of high-grade ore, but free gold was an unknown quantity. A stamp mill was erected and elaborate preparations made to work the ores. The mill was also provided with pans and a modification of the Washoe process was tried; but the raw ore would not amalgamate, and it was determined to calcine the rock. A large kiln was built for this purpose near the mine and the ore was dumped into the kiln mostly in large masses 6 to 10 inches in diameter. Pine wood was abundant at $4 to $5 per cord. The calcining of the ore made it possible to extract from some lots as high as 50% and even 60% by amalgamation, but the loss was so great that a change was determined upon. The stamps were torn out and thrown in the mill yard, and then followed several experiments with cannonball pulverizers and other machines of similar character, which were worse than useless, for the ore is extremely hard and dense. Then a pulverizer of the Cornish roll type was tried, having a revolving screen, and fed through hollow trunnions. This machine stripped its iron gears promptly, and steel gears were ordered, which lasted longer than the iron gears; but the machine was not a success, chiefly because the rock was not broken small enough before being introduced to the pulverizer. Pulverizers were all discarded and the stamps replaced and grinding pans added to the plant. These latter made a noticeable improvement in the saving, but entailed a proportionately greater expense. At last, in '84, all further experiments at the Portland were abandoned.

Later the Buxton Co., a few miles distant and having a similar class of ore, constructed a stamp mill, built a roasting furnace somewhat similar to the kiln at the Portland, but took a step in the right direction by making no further attempt at amalgamation. In this mill the Supt., O. P. Ankeny, installed the bromine process. After fine crushing (wet) in the battery, the pulp was charged in a lead-lined barrel with bromine and the charge revolved until a complete dissolution of the gold was effected. It was then drawn off into a vat, and from that to a settler, and the gold precipitated from the bromine solution by the introduction of sulphuretted hydrogen under the false bottom of the vat, the gold being precipitated in the form of a brownish black powder, which was collected, filtered, dried and melted into bars. This process worked fairly well, but failed to extract a sufficiently high percentage of silver, and was also quite expensive, and was finally abandoned. As will be seen, the bromine process was but a step from a complete solution of the vexatious problem.

The advent of the railroad into the Black Hills in '86 brought about an important change. The following year the railroad was constructed to within a short distance of these mines, and new capital naturally drifted into the country, and, as an outcome, these ores, which for years had defied all attempts to successfully treat them, were soon submitted to a series of experiments, as a result of which they are now worked extensively and to a high percentage of extraction. The processes which have wrought this change and brought into circulation millions of dollars in gold, extracted from these no longer rebellious ores, are the barrel chlorination process, which approximates closely the bromine process introduced by Mr. Ankeny, the cyanide process and the pyritic smelting process. The difference in cost in the operation of these three successful processes is very slight, and all save a high percentage; which will be the most enduring, time only can tell.

The experiments of the earlier days cost no less than half a million dollars, to say nothing of the enormous loss in tailings, and in some cases while experiments were in progress at the Portland mine the mercury "floured" and "sickened" so badly that not only the gold, but the quicksilver, as well, was lost.

W. H. S.

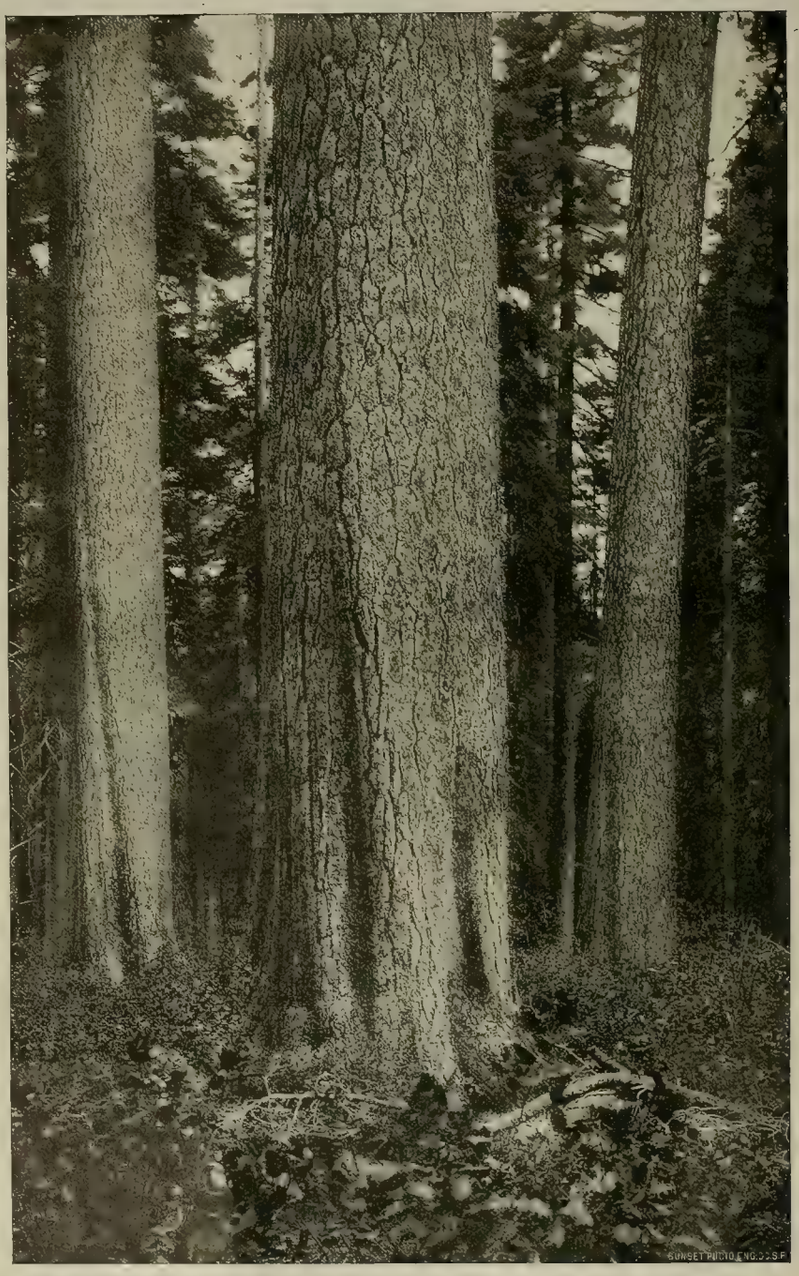
The Forests of the Sierra Nevada.

California people are becoming aroused on the subject of forest conservation and restoration. There are nature lovers here and there who have made touching appeals for the trees; artists who have cast their prayers in the form of impressive views of tree grandeur and forest sublimity and charm, and industrialists who have argued convincingly for moisture conservation and future timber supply. All these friends of our forests have no doubt accomplished much to lead in the state of interest which now rules the public mind, and they must therefore be content with the success of their pioneer work, even if the present rush of popularity should drown their pleading words in the deep sound of a public demand.

Little less than this it really amounts to now. The Miners' Association in their demand that the streams shall not fail; the various municipalities in their protest against anything which may endanger city water supplies; the trade organizations which look forward for general activity and prosperity, have all combined for systematic work for forest protection—work to be continued until its ends are reached. In the northern and southern parts of California the same spirit is being clearly manifested, and the same influences invoked to the same accomplishments. It is a promising time for California forestry—not so much in what has been done as in what will almost surely ensue.

The engraving on this page is in harmony with this spirit. It is a characteristic view in the sugar pine forest of the Sierra Nevada, this especial point being on the McCloud river, in the extreme north of the State, and is illustrative of the great pine and fir region of the Sierra Nevada, which lies along the axis of this great mountain range, from Kern to Shasta counties, and about the inland peaks of the northern Coast Range. Its noblest trees are the *Pinus Lambertiana*, or sugar pine; the *Pinus ponderosa*, the great yellow pine of California; *Picea nobilis*, *Picea amabilis*, and the giant white cedar (*Libocedrus decurrens*).

Botanists divide the great Sierra forests into three belts, depending upon species and altitude. On the lower or foothill belt grow the oaks and *Pinus Sabiniana*. The 6500 square miles of this region extends to an altitude of 2000 feet. The middle forest zone reaches to an altitude of 4000 feet, with an average width of fifteen miles. Here are fine but fewer oaks; here the great yellow pine appears, often 200 feet in height and girthing 20 or 25 feet. Here are the black pine, the red and yellow firs, the fragrant Sierra cedar, and some sugar pines. The third forest zone lies above 4000 feet, extending to 8000 or 9000 feet above the sea, and forms a great mass of varied coniferous forest. The yellow and the sugar pines, the giant firs, spruces, and sequoias rule supreme. Above 9000 feet Alpine species of pines and junipers carry the fringes of the forest to the snow line.



IN THE SUGAR PINE FOREST ON THE McCLOUD RIVER, CALIFORNIA.

Among all the noble conifers the sugar pine (*Pinus Lambertiana*) is easily the first. Single specimens have been measured that were 300 feet high and 40 feet in circumference. Douglass measured one fallen trunk whose circumference was 58 feet. But this most valuable timber tree of the Sierra does not easily reproduce itself, is subject to many enemies, and is rapidly disappearing.

All the mountain counties of California have share in this great forest region. The central regions, being more accessible by rail, and nearer to the markets in city and mine, have their lumbering interests more widely developed and have consequently trenched most deeply upon their timber resources. The most heavily wooded portion of the Sierra forests, aside from the districts around Mount Shasta, are mainly in rough, mountainous country, and in most cases are difficult of access. It is hard to explain to those who have not spent months in the high Sierra or Coast Range the immense reproductive powers of the coniferous forests when given a chance, and also the absolute necessity of some protection. Take the Placer and Nevada districts of the Sierra as an illustration. The forest problems in this district, which is one of the highways along which cattle and sheep are driven into the fastnesses of the Sierra and back into the valleys, are assuredly as difficult and numerous as those of any other part of California. If the leading species will reproduce themselves there, or if some species are gaining foothold, or if a little care and attention would enable the young trees to overcome all obstacles, it seems certain that immense areas in the Sierra elsewhere could also be reforested. The enemies of the California forest are sheep, cattle, the old trees which die, and, felled by the winter storms, break down hundreds of the younger trees, and fires.

AN Idaho journal says the prospecting fever is the only one in the world that leaves in its wake prosperity and plenty, builds cities and railroads, and makes the desert blossom as the rose.

Mining Summary.

ALASKA.

Eureka creek, near Dawson, bids fair to become a Bonanza. Claims 0, 2, 10 and 12 on the left fork are yielding handsome pay. A nugget weighing a fraction over $27 has been found on 33 below upper discovery, Dominion. Nuggets of that size are not common beyond the dome. Sulphur creek is showing up well all along the line. A rich strike is reported on the hillside claim, adjoining 11 above on Last Chance. The creek and hillside claims from lower discovery to 77 below are turning out good. Pay has been located on the benches adjoining creek claims 70 and 77 below, left limit. From Thistle creek it is reported that on 182 above a pay streak 18 feet deep, width yet undetermined, has been located, the pans running from 25 to 85 cents. Bedrock is 16 feet, while the gravel, including pay dirt, is 12 feet.

Kotzebue sound is still one Northern gold field unheard from during the winter. Over 800 miners are wintering there.

ARIZONA.

(Special Correspondence). — The Crowned King mine in the Bradshaw mountains southeast of Prescott is being pointed to as an anomaly in mining, because of the discovery of free-milling ore on the 500 level. It is cited as the "first case on record" where a vein changed abruptly from a very base ore to a free-milling ore with depth. While this condition actually exists it is rather misleading. At the surface and for some distance below it, the Crowned King vein was oxidized and quite free, but lower iron and zinc sulphides appeared in abundance and the ore became very base, but a small portion of its gold being free. The occurrence at this time of quartz carrying large amounts of free gold and very little sulphide mineral is of purely local character and signifies nothing in particular.

Prescott, A. T., April 1st, '99.

The Helvetia group is thirty-one miles southeast of Tucson. It comprises thirty-eight claims, and has been bought by Boston, Michigan and Chicago men; a company has been organized in New Jersey, capital $5,000,000. It is claimed that an expenditure of $250,000 will equip and bring the mines to a production of 120 tons of 9% ore per day, or 21,600 pounds of copper. A 60-ton smelter is to be built. Under present conditions mining has cost $2.31 per ton; under modern equipment, it is estimated, this can be reduced to $1.50, including delivery. The cost of smelting is now estimated at $4, which can be reduced to $3.50. One of the men employed to report on the property says that copper electrolytically refined ean be laid down in New York at less than 6 cents a pound.

Yuma *Sun*: S. M. Smith and H. W. Blaisdell have gone to the King of Arizona, near Yuma, to look after erecting the mill and cyanide plant.

CALIFORNIA.

Alpine.

There are three stamp mills in this county, all of which are idle.

Amador.

On good authority it is asserted that work at the Alma mine, Jackson, will not be resumed very soon.

It is rumored that a full force will soon be at work again at the Amelia mine, near Jackson.

At the 1300 level good rock has been encountered in the Zelia, near Jackson.

Amador *Dispatch*: Power drills have been placed in the east shaft of the Kennedy mine, at Jackson.——At the Pocahontas, at Drytown, crosscutting at the 315-foot level is in progress; also in the California mine on the 400-foot level. The crosscuts are being driven through the slate to the east. The quartz taken from the crosscuts supplies the 10-stamp mill. Sinking will commence April 15th. It will be sunk to 800 feet.——The Butte Mountain Co., Mr. Marsh Supt., have the ledge in their tunnel; it shows no free gold, but prospects well, and is heavily charged with sulphurets.——H. Osborne, the owner and promoter of the Peerless mine, on the Badarraco ranch, says work will be resumed soon.

Amador *Dispatch*: Copper ore has been found on the ranch of E. Fink on Stony creek west of Jackson. There is said to be a large vein of the ore.

Butte.

A new industry is being developed at Chico from paint deposits recently discovered. A company to manufacture these paints has been formed.

Calaveras.

(Special Correspondence).—Some mines of promise are being opened up in the Salt Spring valley. The mines are scattered along this valley between the Bear Mountain range and Gopher ridge from the vicinity of Valley Spring to Pine Log and beyond, a distance of fifteen miles or more. The mountain ridges are composed chiefly of diabase. Along the east side of the valley are large and almost continuous outcrops of serpentine, and west of this is black slate of the Mariposa formation and amphibolite schist, with intruded dykes of a gray rock probably allied to diabase, but later than the massive diabase of the neighboring mountains. The gold-bearing veins occur at contact of these dykes and slates, or wholly in the dykes themselves. In the serpentine rocks, and near them, are found copper ores. The mines of Copperopolis are on this belt, two and one-half miles southeasterly from Pine Log.

Copperopolis, April 2nd, '99.

Supt. Lucas has found good ore in the Garner mine, near Big Bar bridge, on the Mokelumne river.

The Angels mine at Angels is to be run by electricity, furnished by the Blue Lakes Co.

Citizen: It is reported on good authority that the Lamphear mine in Spring gulch, one mile from Mokelumne Hill, which has been idle so long, will start up the 1st of April.

Amador *Republican*: It is reported on good authority that the Sheep Ranch mine is to be equipped with a new hoist and a mill and the mine to be reopened. The shaft is about 1200 feet deep.

Del Norte.

Copper ores are found near Low Divide, ten miles east of Smith River Corners, near Bald mountain. The belt runs northward into Oregon. The formation is serpentine.

Del Norte *Record*: The Ocean Beach placer mine below Crescent City has been closed down.

El Dorado.

The Taylor mine has been equipped with a cyanide plant for treating sulphurets and tailings.——The Josephine mine near Volcanoville is again being worked after a long idleness.

Placerville *Nugget*: G. B. Rymal and G. Jones recently took out $1600 from a pocket on their claim on Pilot hill.

Fresno.

Miners can still make small wages drifting the gravel bars on the San Joaquin river, above Pollasky.

Humboldt.

Yreka *Journal*: Extending southward from the Siskiyou county line into Humboldt county is a mineral country of which little is known; the development is limited owing to its inaccessibility except on foot or horseback.

Inyo.

A. J. McCarthy of Los Angeles, Cal., is putting a cyanide plant in at Pigeon Springs to work tailings.—— E. Smith has struck water in a shaft recently sunk at Big Pine and will make a mill run.

Kern.

Randsburg *Miner*: The Yellow Aster Co. is building a machine shop near the mill.——The Eureka mill has been bought by Kinyon Bros. The larger proportion of the dump at the Kinyon mine will pay to mill, and when the mine cannot supply enough ore it will be kept running on the dump.

Los Angeles.

On Mount Gleason, seven miles southwest of Acton, are bodies of magnetite, on which little development has ever been done. In the vicinity are gold-bearing quartz veins, containing free gold and iron sulphurets said to be high grade in gold. These latter have considerable development, but have never paid for some reason—perhaps not altogether the fault of the mines.

Los Angeles *Times*: The Santa Fe Railroad Co. has commenced sinking two new oil wells near Fullerton.——The Puente field is steadily developing. A large gas engine is being put in to furnish power for pumping. Natural gas will be the fuel used.

Los Angeles *Mining Review*: The Red Rover Co., at Acton, will equip and develop the old Topeka mine, near the Red Rover.——The Escondido mine, seven miles from Acton, is being reopened. It was worked years ago to the water line and abandoned. The rock was worked in arrastras.——There is activity all over this much-neglected district, but a great deal of the work is of superficial character.

Marin

It is reported negotiations for the copper mine near Dog Town, in Union gulch, are in progress.

Nevada.

Union: A new hoist and pumping plant is to be installed at the Brunswick mine, near Grass Valley. The friction will be 7 feet in diameter with 12-inch face. The drum will be 4 feet in diameter. The friction will be separately keyed on the shaft. There will be a paper friction 18 inches in diameter and 12-inch face, the drums to be run by a 7-foot water wheel. The rope sheave will be 7 feet in diameter. The pump will be a 12-inch Cornish plunger.

Republican: The Grand Victory M. Co. expects to begin work at their mine at Fall creek shortly.

Placer.

At the Crandall mine near Auburn is a 5-stamp mill of 1100 pounds which falls 105 times in a minute; water is brought 2131 feet and has a fall of 240 feet. The concentrates will be shipped to Selby's for reduction. If the returns are as good as expected fifteen stamps will be added. The main tunnel is in 500 feet on the Cox & Denton (known as the Crandall ledge). At the face the ledge is 6 feet wide. It is an east and west ledge and dips to the south. The company owns five veins—the White Goose, Clough, Crandall, Hunter and Sacramento. At the mill these veins are nearly parallel, but they meet at no great distance on the east. Twenty men are employed.

Colfax *Sentinel*: A number of hydraulic mines have been able to commence work, owing to rain.——The water in the North Fork of the American was higher last week than since the flood of '90.——River bar mining will be profitable the coming season. The flood has lowered the tailings in the North Fork about 2 feet. Nearly the entire bed of the river is held by location from the Yankee Jims bridge to a point opposite Gold Run. For the past two years the floods have been insufficient to move the tailings. Three years ago miners on river bar claims cleaned up $3 per day for the season; some of them made runs that returned $8 per day to the man.—— Supt. McAulay is piping in the McCall pit at the Mayflower mine, near Forest Hill. A permit was secured in '97, but the water supply has not been adequate until now. The restraining dam is located in Black Oak canyon. Several men are employed in the drift mine. ——The Big Gun hydraulic mine at Michigan Bluff is working. It is owned by A. Dixon and others.——The flood carried away the boarding house at the Cash Rock river mine, on the Middle Fork of the American river.—— At the Red Point mine, near Damascus, there are fifty-nine men on the payroll. The main tunnel is now in 12,700 feet. An average of 108 cars of gravel are mined per day. Seven horses are used in hauling trains.—— Supt. H. F. Adams of the Derby mine, between Centerville and Sunny South, says the new lower tunnel is in over 900 feet.

Placer *Herald*: The Bouks are taking out good ore at their mine near Bloomer Cut. The vein averages 14 inches.——The rock at the 600-foot level of the Hathaway mine, near Ophir, proves richer than any other part thus far opened up.——The Gold Blossom, near Ophir, is working a large force of men.——The Herman mine, six miles north of Deadwood, has been shut down for thirty days. The pumps cannot handle the water.——The Morning Star at Iowa Hill employs sixty-five men and yields its regular dividend.——The old shaft at the Coppertown mine will be cleaned out and sunk deeper.——The Evening Star mine with all its machinery on Rock creek has been bid in by H. Bernnardt. This mine was sold a year ago by J. Heenan for $5000. Since then a plant costing $7000 has been placed there.

Republican-Argus: A good strike is reported from the Pine Tree mine, near Newcastle. The vein is 4 feet wide and carries galena and free gold.

Plumas.

Bulletin: Work is to be resumed on ten mines of the Elizabethtown Gravel M. Co , on the Kellog ranch near Quincy, about April 1st. The company has a 60 H. P. boiler, 40 H. P. engine, a hoist, a 10-inch Cornish pump and three steam steam pumps in reserve. There is a double-compartment shaft 100 feet deep with a tunnel 120 feet extending towards the channel. C. R. Merriam is Mgr.

Riverside.

Johnson & George, lessees of the Good Hope mine, four miles southwest of Perris, are working some of the most valuable ore that has ever been found in that mine. They have been offered a large sum for the ore taken out so far this month, but have refused it.

San Bernardino.

(Special Correspondence).—The Gold Bar mine is developing into a promising property. A. G. Campbell, who owns the Boomerang and other claims on the opposite side of the ridge from the Gold Bar, bought the latter mine some time ago and has developed it. The fissure ranges from 1 foot to 20 feet in width, with a pay streak from a few inches to 10 feet in width. The ore is partly free near the surface, but in depth is heavily charged with the sulphides of iron, copper, lead and zinc. The ore is worth $20 to $40 per ton. The Gold Bronze mine, operated by C. A. Stilson and others, is a continuation of the Gold Bar, though having a different strike, the vein curving between the workings of the two properties. The ore in each is similar and the vein characteristics the same in both.

Vanderbilt, March 31st, '99.

At Ivanpah, the Ivanpah Copper M. Co. is reported to be daily smelting about six tons of copper, 95% fine.

San Diego.

The Ruby 5-stamp mill at Banner is being removed to the Ranchita mine south of Banner.

Union: At Hedges the Golden Cross M. Co. has but fifty stamps in operation in the 100-stamp mill, and a spirit of economy pervades the camp. There are 200 men on the payroll. No new discoveries have been made in that section lately. Receiver C. W. Pauly is kept busy in directing the affairs of the company.——J. K. Vanatta of Colorado Springs, Colo., one of the new owners of the Elevada mine at Banner, who with others purchased the mine several months ago, has organized the Smoky City M. Co., with a capital of $250,000. The mine had been partially developed and men were put to work cutting the tunnel already started 379 feet below the main shaft and is now in 200 feet. Mr. Vanatta stated that the ore averages about $20 a ton. It is probable that an electric dynamo and hoist will be put in.

Shasta.

The Frue mine, on Coffee creek, is being developed under contract.

Free Press: W. M. Dale has purchased from A. R. Meyers the Lucky Spot mine, one mile west of Cow Creek smelter.——The Blue Jay mine, on Coffee creek, which attracted a great deal of attention a year or two ago by reason of the rich pockets found near the surface, is now producing milling rock. The development disclosed a sulphide vein in the lower tunnel. ——Four men are employed at the Eureka Tellurium mine.——The Washington mine, near French gulch, is being worked by M. Sheehan, who is working on the lower tunnel; he has taken out some good rock of late. The 5-stamp mill is being run constantly and is operated by the company, who work leasers' rock for $3 a ton.——It is said that there is hardly a foot of ground in the Flat Creek mining district not included in a mining location. One day recently seventeen notices of location of quartz claims in that district were recorded. Of that number, W. Candrick has eight claims, C. D. Galvin has six, E. V. Cartner two and H. D. Crandall one.——The Golinsky-Clendenin copper mine, near Kennet, is working twenty to twenty-five men. They are driving a crosscut tunnel 200 feet below the croppings, now in 55 feet. Mr. Kemp has let a contract to G. Bjork to drive 100 feet.

Democrat: The Gambrinus mine, at Whiskeytown, started up this week. A tunnel 100 feet below the old workings will be run to drain the mine. There is now in the mine 500 feet of tunnel. There are several veins on the property, ranging from 2 inches to 4 feet in width.——The main shaft on the Mount Shasta mine is now down 250 feet, and a gasoline hoist is used, but the owners intend to put in a hoist of greater power. An average of twenty tons of ore a day is shipped to the Keswick smelter. Some of the ore runs as high as $400, the lowest $25.——Work will be resumed on the Dun Bros. mine, on the apex of Nigger Hill, a mile west of the Keswick smelter. The main prospect shaft is down 80 feet and will be sunk to 300. This mine has yielded high-grade ore; the gold values are principally in sulphurets.

Searchlight: Fifteen stamps are dropping at the Uncle Sam, near Kennett, and according to Gen. Mgr. Dakin 700 tons of rock were crushed with very satisfactory results. Since March 15th new ground has been opened and the returns from that source are encouraging, some of it going to $10 per ton. The mill and the mine are being worked with three shifts.

Sierra.

The Bonanza M. Co. has conveyed all of its property at Sierra City to the Mining & Investment Co., and all suits against the former have been dismissed and litigation settled up. Mgr. Pinney is having the 40-stamp mill repaired.

The Comet mine, in Jim Crow canyon, is being developed by Eastern capital, G. F. Taylor Mgr. Considerable money will be spent on the property this summer. A large vein has been found in the tunnel which prospects well.

Siskiyou.

A quartz vein carrying galena, on the ridge between Fox and Boulder creeks, four miles west of Callahan, has several superficial cuts on it.

Yreka *Journal*: The Aromas Co. at Salmon river has a small force employed until the ditches are fixed up again.——The Salmon River Co., which bought the Klein mine at Salmon river, keeps a full force of miners at work.——The Chicago M. Co. has purchased several mines in the Cottage Grove district, on Klamath river near the Humboldt county line, where there is abundance of water all the year round, and rich placer ground.—— The Oregon G. M. & M. Co. has purchased the Ah Ock mining property and ditches at Happy Camp.

Trinity.

Redding *Free Press*: It is reported that the ledge was struck in the Chloride-Bailey mine near Junction City in a crosscut some time last week, at a point between 250 and 300 feet below the old workings. The Chloride-Bailey is owned in San Francisco by O. O. Howard Jr. and F. E. Ware, owners of the Mount Shasta mine, and others.——The Temple tunnel at the Integral mine, twenty-two miles northeast of Trinty Center, has been closed down. They are working six men, two shifts, in the Castella tunnel. The latter is now in a distance of 2165 feet.

Tuolumne.

It is rumored that the owners of the Rawhide mine, four miles west of Sonora, and the App mine at Quartz mountain, are endeavoring to sell these properties, to which particular attention has recently been attracted by reason of litigation between the owners, W. H. Martin, John Ballard and W. A. Nevills. Litigation has been suspended pending the result of the negotiations now in progress. The price asked for the consolidated properties is said to be $2,000,000.

Banner: Thirty stamps are now dropping at the Black Oak mine near Soulsbyville. The shaft will be sunk 250 feet deeper, making it 1000 feet deep.——It is reported that Jas. and Jos. May have cleaned up a $10,000 pocket in their claim below Saw Mill Flat near Columbia.——A rich bed of gravel has been discovered on the Brunson ranch, below Chinese Camp. The supply of water is less than is required to do the work at present. The gold is coarse and high grade.

The Gerrymander mine at Sonora is about to resume operations. The shaft now 115 feet deep will be sunk to 315 feet. A contract for 200 feet will be let. An addition to the mill is contemplated the coming season.

Democrat: Pocket mines have been discovered near O'Byrnes' Ferry. Recently a miner and a sheepherder went to work and in a short time took out $600, and since have taken out from $10 to $30 every few days. A number of claims have been located. The district is on government land.

Independent: At the gravel mine near Crystal Palace Cave, owned by Abel, Napoleon & Smith, $400 worth of nuggets were picked up after the heavy rains from the gravel which had been piled up during the dry season.——The Columbia E. & T. Co. are setting up their machinery on the Jolly ranch, about 500 yards north of the first workings. ——The ditch from the Philadelphia Diggings, near American Camp, to the south fork of the Stanislaus, a distance of seventeen miles, has been completed and hydraulicking commenced. The scarcity of water heretofore was a great drawback. Twelve men are employed.

COLORADO.

CLEAR CREEK COUNTY.

Mining Gazette: Dickson Bros. have started work on their Cumberland. It mills about $30 per ton and the vein is 3 feet wide.——Hawk Bros. are stoping ore from the Little Cora that runs in mill sample six ounces gold per ton. The vein is thought to be the extension of the Whale.

Silver Standard: The extension of the Pomeroy tunnel through Gray's Peak is again being agitated. —— Considerable ore was shipped from the Pelican this week.——Large shipments of ore have been made from the Smuggler this week.——Davis & Alan have commenced work on the King and Queen lodes in Brune gulch.——C. Hansen had a mill run of 189 sacks of ore from the Corroy City last Saturday which gave 276½ ounces silver per ton.——There is a large quantity of ore at the Dunderburg awaiting shipment.

GUNNISON COUNTY.

(Special Correspondence).—A suit involving a one-eighth interest in the Vulcan mine, near Gunnison, in which J. A. Heimbaugh and J. M. McDougal were the principals, has been settled out of court, Mr. Heimbaugh having purchased the McDougal interest for the sum of $7500 cash and the dismassal of the two suits pending against the McDougal interest. One suit was pending in the District Court of this county and the other in the

Court of Appeals. This will end what promised to be a very bitter and hard fight through the courts.

The mine has not resumed work since the recent trouble, a pump man and two men in the mine, catching up some bad places where it had to be retimbered, being the only ones employed.

The Good Hope and several other properties near it, that were affected by the recent Vulcan trouble, have again resumed work and will, as soon as the snow is off, increase the force of men and also the output.

A deal has just been consummated whereby the Midland property has fallen into the hands of Denver people, who are able to put it on a paying basis, as the property is a good one. They have good ore and plenty of it and a Huntington mill of about fifteen tons capacity. The mine is shut down at present, but will start up as soon as supplies can be gotten to the mine, which will be about a month, on account of snow.

The mines at Pitkins and North Star are only working few men, as they have everything full of ore and cannot haul it out, on account of the soft snow, which is the case with about all the mines in the silver-lead belt. There are a number of good properties in the belt that will be opened this year and will add much to the output of wet ores from this county for '99.

Great activity is expected in the early spring in the extreme northern part of the county, where a good many promising copper properties are situated. Most all of them carry good values either in lead, silver or gold. There are some good zinc properties in the same belt, and, with the present price of that metal, they should not be overlooked.

Gunnison, Colo., March 26th, '99.

(Special Correspondence).—The Graflin tunnel will resume work at once, Mr. Graflin having returned from Chicago and all arrangements perfected whereby the tunnel will be pushed forward, and, unless all signs fail, before next winter it will be one of the big mines of this county. While in the East he also made an arrangement whereby he will work another property near Vulcan, where he already has a force working, and is confident that he will ship ore before thirty days. I did not learn the name of the new property acquired, but it is across the gulch from the Vulcan mine and a little farther down.

Lincoln Ball has returned from Denver and will push work on his several properties near Ohio City, and will have plenty of silver-lead ore to ship when the snow is gone.

G. W. Griffey has returned from Iowa, he secured the needed funds to push forward the DuBoise tunnel to cut the several large veins that they will reach in the next few hundred feet. He will also work the big vein discovered last fall on the east side of the gulch. The vein was found in a crosscut and is said to be 30 feet wide and will run $15 in gold. It is but a short distance to a good mill site, where water power can be obtained for all purposes at the foot of the gulch where it enters Cebolla creek.

A contract for 400 feet of work has been let to Pueblo people on the Iron Silver mine near Gothic. This property belongs to the Copper Creek M. & M. Co. When finished it will give them 1400 feet of development on the mine. The company owns fifteen claims in the vicinity. The property is a low-grade silver mine that will likely need concentration.

The Mgr. of the Doctor mine was in from Aspen this week and says his company will put in a concentrating plant this year having a capacity of seventy tons daily. Much of the dump material can be worked over at a profit. The mill will be built on the old town site of Moscow, where water power is to be had.

It is reported that a Mr. Brown will succeed the old foreman, Mr. Likorish, at the Vulcan mine. It is said that a good deal of dead work must be done to put the mine in good condition. The mine will soon start up again and ship high-grade ore. The mine will also ship large quantities of sulphur, which is from 85% to 97% pure.

Gunnison, Colo., April 1st, '99.

LAKE COUNTY.

The total production of Lake county for '97 was $6,447,073.65; for '98, $8,160,647.32. The county produced $4,117,533.48 in silver—nearly one-third of the entire output of the State. In lead Lake county leads production, being credited with $1,304,803.72—nearly one-third of the output of Colorado. The county produced $665,274.48—more than half the output of the State.

Salt Lake *Tribune*: A mining enterprise backed by large capital has been closed at Leadville. The Valley, Forest Rose and Dispute lodes on the western slope of Little Ellen hill have been leased by a syndicate of Chicago capitalists with the intention of putting in a new plant of machinery and sinking the shaft 500 feet. The lease is for three years.

Leadville *Miner*: There is an undeveloped field west of Leadville near Walta, Tennessee Park, Strawberry and Little Union gulches in which are vast deposits of mineral.——The Winnie D. shaft is down 275 feet in fine mineral. Drifts are to be run on the contact.

MINERAL COUNTY.

Denver *Post*: The Nelson tunnel is under the Last Chance shaft and 15 feet of ground separates them, which will be rapidly drilled to allow the large body of water in the upper workings to drain itself. This has been the cause of light shipments.——The Alpha, one of the Sunnyside group, has uncovered a body of high-grade ore on the 200 level, carrying silver, lead, zinc and a small percentage in gold.

SAN JUAN COUNTY.

Silverton *Standard*: A number of mills are to be erected the coming season as a result of successful experiments in mills that are now operating on low-grade ores. The largest of the proposed mills will be for the Tiger mine in Arrastra basin, to concentrate 100 tons of ore daily.——T. J. Hurley, president of the Occidental M. Co., says a reduction plant will be erected on or near the Occidental mines the coming summer.——J. H. Shockley, Supt. of the Four-Metals M. Co., has a number of samples from the Lackawana mine for experiment to determine what kind of plant will be necessary.——The Veta Madre people have plans and specifications for a mill on Galena mountain.——J. H. Collins, president of Gold Bug-Repeal M. Co. on Bear creek is of the opinion that the veins of concentrating ore on Cement creek can be more profitably milled than ores at Bear creek and will probably build a plant on the property in Cement creek.——The Red and Bonita M. Co. is contemplating the building of a mill on its Cement creek properties.

IDAHO.

J. H. Martin is superintendent of the work being done by W. A. Clark of Montana on the Sunset at Wallace. Three shifts are being worked there and the tunnel is being run as fast as possible with hand drills. An air compressor will be put in. From the mouth of the tunnel to where it is calculated the vein will be cut is about 2600 feet.

It is the understanding that the Bunker Hill & Sullivan will erect a concentrator in Government gulch this year to work the ore from the Silver King.

The men employed clearing away for the erection of the Big Buffalo mill in Winslow canyon have walked out on account of a reduction of wages from $4 to $3 per day. The erection of the mill will be delayed until other men can be secured.

The drift on the Sixteen to One at Wallace is now in 30 feet from where the ledge was cut and the body of clean ore continues 3 feet in width. Slow progress has been made drifting, the amount of clean ore making it necessary to prepare room to store it, as it will be impossible to ship any for a month or more yet. The ore assays 66% lead and forty-five ounces silver. It is reported that $250,000 has been offered for the mine: $10,000 down and the balance in different payments. As there was more than enough ore in sight to make the first payment and there would be time to take out the balance before it became due, the offer was refused.

Statesman: It is reported that the Philadelphia Co. has bought from G. A. Williams and others a number of claims on Grimes creek and will commence operations soon with W. O. Taylor, Supt. It is understood that $40,000 was paid for this ground. They will put on one or perhaps two dredges.——The Warm Spring dredge was operated at an expense of 2 cents a yard, from 1500 to 2500 yards being handled a day. The average yield was $420 a day, while on one day $1000 was cleaned up. The creek has been prospected on both sides for a long distance, and there is enough ground to keep the dredge running for many years.

Caldwell *Record*: The dredge near G. Paul's place is handling 2000 yards of gravel daily. It is equipped with electric lights. One man controls the entire plant from his position at the bow of the boat.

The Empire State-Idaho M. & D. Co. is proposing to run a tunnel from Government gulch at Wardner into the Last Chance ground, cutting deeper than any of the present works and which would necessitate building a new concentrator on that side of the ridge. It will be a mile in length and may be as much as a mile and a half. While it will be surpassed in length by the two-mile Kellogg tunnel of the Bunker Hill & Sullivan M. & C. Co., it will be longer than any other tunnel in the Cœur d'Alenes, the next being the 300-foot tunnel of the Mammoth and the Standard and W. A. Clark, each one about a half mile long.

Lewiston *Tribune*: The bonding of the Great Eastern copper property for $60,000 could not be divulged until now. The property lies eighty miles up Snake river and forty miles below the Peacock group. The mine has been penetrated for 50 feet. Shipments to different smelters returned 23% copper.——The sale is reported of the Star group of mines on Rabbit creek, in the Mallick district, to the De Lamar syndicate. J. J. Bennett of De Lamar and D. B. Huntley, Mgr. De Lamar mines, will go to the property and make an examination and tests of the properties. The bond includes four quartz, two placer claims and two water rights. The ledge is 60 feet wide through the four claims, widening at one place to 140 feet. The assays run $5 to $87.

MONTANA.

Counsel for the Boston & Montana Co. asserts that the company, at the present price of copper, is earning $30,000 gross and $17,000 net per day; putting the present price of copper at 16⅝c, a gross of $30,000 a day would be 180,000 pounds a day and 56,760,000 pounds a year of 312 working days. Seventeen thousand dollars net per day would yield $5,304,000 for the year, about $36.50 per share. Seventeen thousand dollars net on $30,000 gross would show operating expenses of 43¼%, and that expenses of 16⅝c gross per pound would show a production cost of about 7⅞c.

Inter-Mountain: Reports from Silver Lake, the scene of the Washoe Copper Co.'s tunnel which is being driven into the lake to secure water for the proposed new smelter at Anaconda are discouraging. Quicksand was encountered and also a large body of water. Different kinds of pumps have been tried, but without success. There is talk of abandoning the tunnel and starting a new one away from the canyon bed.

Helena *Independent*: The Mantle mine, located on Cataract creek, near Basin, is now being operated by J. Madden, under lease, who is building a steam stamp mill, which is expected to be crushing ore by April 1st. Developments on the mine are being rushed.——The main shaft in the Hope mine at Basin has reached the 600 level, a station has been made and the crosscutting commenced. The ore is the same character as that found in the upper levels.

NEVADA.

The Mineral Union, Ltd., is building a leaching plant at Good Springs, Lincoln county; capacity, 100 tons of ore daily. H. Hirsching of Denver, Colo., is Mgr.

The new Searchlight district is now ready to ship gold ore.

Vulcan Copper Mining and Smelting Co. is the title of a company incorporated under the laws of West Virginia to operate in Santa Fe district, Esmeralda county, where the company recently purchased a group of mines. The general office of the company is in Chicago, Illinois. The ore is a carbonate of copper and carries a small percentage of gold and silver. The mines are thirteen miles northeast of Sodaville. A smelting plant is to be built.

There are several changes in the mining law made by the recent Legislature, the most important being intended to simplify the method of making a location. The form of the notice is not essential, provided the stakes are properly set; the time for completing the location work is extended from 90 to 120 days, and it is no longer required that affidavit be made to the performance of assessment work.

The hydraulic pumping plant at the C. & C. shaft as reconstructed resumed working last Saturday. On the 4th inst., Mgr. Ross wired: "Water is 118 feet below 1750 level and 144 feet below the Sutro tunnel drain boxes and being lowered at the rate of 6 inches per hour. The elevator is working steadily without vibration."

The lowering of the water is noticeable at the Combination shaft, 3400 feet distant to the south, and at a winze in the Hale & Norcross, 720 feet to the northward.

Under date of the 6th Mgr. Ross sent the following: "Shut down the elevator three hours last night; water rose 21 feet. At 6:30 this morning the water was within 10 feet of the lowest point reached, or 132 feet beow the 1750-foot level and 158 feet below the Sutro drain boxes. Will run the elevator only enough to keep the water to about this point until water is drained from bonanza stopes. The water going down slowly at all points when measured. Elevator is running quite steadily."

It is understood to be the intention that when the water has been lowered to a point 200 feet below the Sutro tunnel connection, the present limit of the elevator, there will be a delay rendered necessary to install new extensions for lowering the water an additional 200 feet. While these changes are being made the pump will hold the water at the first 200-foot point.

Virginia *Chronicle*: A marble and granite quarry is added to the industries of Humboldt county in the vicinity of Winnemucca.

Pioche *Record*: Searchlight is close to the California line in Lincoln county. Considerable ore is being produced. Five mines are being worked and a mill is being built. There are about 150 men employed and California capital is developing the mines.——The camp of Pioche to-day offers opportunities for smelting propositions, as the ore is a combination of silicious iron, lead and lime gangue.——The old Silver King district is forty miles north from Pioche in the Patterson mountains. It contains large deposits of galena.——The Stateline district, recently discovered in Lincoln county, has a number of producing mines. Salt Lake capital is being invested.

NEW MEXICO.

White Oaks *Eagle*: The shaft of the Old Abe at White Oaks is now down 1050 feet and from 850 to 900 feet is all in ore, and at 1050 the pay streak was found by running a short drift. A number of seams from the vein have been followed and pockets of free milling ore have been found; also gold masses weighing seven pounds. The mine has a 20-stamp mill. Water is pumped a mile through 3-inch pipe. The company also owns a coal mine which supplys fuel for the works and is sold to others in the neighborhood.——An interesting occurrence of gold in gypsum is reported from the Old Abe mine at White Oaks.

OREGON.

Baker City *Republican*: Rich ore has been found in the Devil's Dream and the Maiden's Dream, two mines seven miles from Sumpter, now under bond to W. L. Vinson of Seattle.

SOUTH DAKOTA.

The Deadwood and Delaware pyritic smelter at Deadwood treats 700 tons of charge every twenty-four hours and is one of the largest if not the largest pyritic smelter in the world treating gold ore exclusively.

Pioneer *Times*: The Sunset shaft in Ruby Basin is down 300 feet in sandstone, and it is thought will soon reach ore-bearing quartzite.——Work on the Diamond mine on the Two Bit side of the Lexington hill has been suspended on account of water. The shaft is on a fissure in porphyry. The owners expect to sink to quartzite. It is thought the vertical vein will lead to a rich shoot of ore in the quartzite.——J. D. Hardin of Deadwood says that within sixty days work on a reduction works on Redwater creek, north of Black Hills and about eight miles from Spearfish, will be commenced.——The Delaware shaft in Ruby basin is down 410 feet and sinking going on.——The shaft recently started on the Gold Edge Co.'s ground in Strawberry gulch has reached a depth of 40 feet following a vertical vein that now reaches across the shaft. The ore is similar to that in the Gilt Edge and Dakota Maid and samples from $6 to $7 per ton.

UTAH.

Salt Lake *Tribune*: A strike has been made in the New Guinea claim of the Tidal Stream Co.'s ground, in the Erekson district, West Tintic, Tooele county. Samples assayed 52% lead and 69 ounces silver, one carrying as high as 4018 ounces silver. The vein has now been followed 160 feet, all in ore.——The new mill of the Daly-West, at Park City, made its first run April 1. It has a capacity of 100 tons per day and will be in steady operation.——It has been reported that the control of the Mercur M. Co. had been sold to Boston parties.——The Four Aces, at Silver City, is said to have uncovered good ore in the north drift on the 630-foot level. There is also a good streak of lead and silver exposed in the south drift, same level.——The Phœnix group at Bingham has been bonded for $125,000. A large amount of ore is in sight.——As a result of the recent sheriff sale of a part interest in the Yosemite No. 2, that property has passed to the control of Genter, Airis & Bamberger. They propose to put in pumps and necessary machinery and work the old property on its merits. It would be a good thing if other old Bingham properties with a record would fall into the hands of men able to operate them. There are many formerly good producers, now lying with old works caved, that never had openings deeper than prospect holes.——Since D. J. Cook & Co. took the upper workings of the Winnamuck under lease a month ago, the mine has been put in order, aside from handling a large amount of ore. Two hundred and fifty tons of second class went to the Dewey mill. There are twenty-five tons at the mine awaiting cars. Part is first-class and part was run through a jig at the Winnamuck mill.——A strike in copper, gold and silver in the Salt Valley country, on the Grand river, north of Moab, is attracting attention. Within a few weeks rich ore will be shipped.

Eureka *Republican*: The Grand Central mine is temporarily shut down, pending the installation of the new hoisting plant.——Ore shipments from Tintic for week ending April 1 were eighteen cars of concentrates.——Fourteen miners are now employed in the Eureka-Hill mine. Work is now confined to prospecting with fourteen Burleigh drills.——The Eagle-Blue Bell mine is reported in good condition. A winze is being sunk on the 130 on a 5-foot vein in which there is 18 inches of ore running from $80 to $120 in gold and six ounces silver, from which a ton and a half is being taken out at each shift. Drifting is also in progress on 200.

Park *Record*: There has been an increase in the force at the Daly-West mine recently. Ore is being hoisted steadily, and the mine is looking well. As development work progresses, greater ore bodies are uncovered.——Woodward & Loofbourow, who have a two years' lease on the West Ontario group, are drifting on the vein and taking out good ore. They have been working all winter, and will ship when the snow disappears and teams can travel the mountain roads.——Bunce & McClaren, who have been working all winter on a lease on Crescent ridge, have a 3-foot vein of carbonate ore, and several tons ready for shipment.

WASHINGTON.

(Special Correspondence).—A mineral field which is beginning to attract attention is known as the White Horse district, in Snohomish county. In this county more than twenty lodes having veins of ore from 2 to 10 feet in width have been discovered.

The character of the ores in different parts of the district differs, as do also the formations in which they are found. On Gold mountain, which is probably the richest section of the district, the lodes are less than 600 feet apart, on an average, in a belt more than a mile wide. The ore contains gold, copper, silver, and in one case at least, quicksilver.

There has been but little development work done, but surface assays give from $3 to $31 in gold, from a trace to five ounces silver and 5% to 14% copper.

The country rock is a variety of slate with some hornblende, and the mineral veins accompany dykes of porphyry. They are vertical, have a strike due east and west and are well defined and continuous, seven claims having been located on a single lode with distinct outcrop on each claim. These deposits are easy of access and ores can easily be treated.

Gold mountain rises from the east bank of the Snake river to a height of 3000 feet, and some of its mineral veins outcrop from water level to the summit of the mountain and down the opposite side. Just across the river from Gold mountain is a level plain, on which Darrington, the postoffice of the district, is situated, being only 565 feet above sea level. This plain is well suited to the purpose of townsite, smelting plants, etc. A supply of pure water in abundance for all purposes is near and easily available. It is forty-five miles to Puget Sound, thirty-two miles to the Seattle & International R. R., at Arlington, and twenty miles to steamer navigation on the Skagit river, with a wagon road to the last named point.
